Experiments by Bartlett and Doty on macaques paved the way for the first human experiments in the early 1990s, in which they demonstrated that the minimum spacing between two electrodes to elicit distinct phosphenes is around 500 μm. Schmidt et al. (1996) implanted a 34-electrode array in the visual cortex of a 42-year-old patient who had been totally blind for over 20 years and showed that the patient was able to recognize simple patterns delivered through the intracortical microstimulation.

Dobelle and his colleagues (Dobelle, 2000) announced the first cortical implant that provides independent mobility to blind people. Initially, the 68-year-old subject could not recognize letters or numbers. However, after 3–4 h learning sessions 2–3 times a week, the subject was able to recognize a character inscribed in a 6 inch (15.24 cm) square at a distance of 5 feet, which corresponds to a visual acuity of 20/1200. In 2001, a zoom function was added to the camera improving the acuity to 20/400. The subject was able to take the subway by himself and navigate in a room with obstacles. That said, the success cannot be attributed to the implant alone, as an ultrasound telemeter was mounted on the camera to help with obstacle avoidance. More recently, wireless implants have been developed (Troyk et al., 2003; Hosseini-Khayat et al., 2012) that eliminate the transcranial cables and thus facilitate the surgical procedure.

2. Design concept

As is the case with other visual neuroprostheses, a camera captures images and sends the information to a processing unit, which enhances the contrast and reduces the resolution of the images. The unit then transmits a control command to the implant which then electrically stimulates the visual cortex. In theory, three parameters determine the quality of a pixelated image: the number of pixels, their density, and their range of achievable intensities. The number and density of pixels achievable with a cortical implant is related to the number of implanted electrodes and limited by the density of the electrodes and the spread of currents, which determines how distinct the phosphenes are elicited by two adjacent electrodes. There are many technological hurdles to producing arrays that are dense, robust, and biocompatible. Intracortical implants require complex and risky surgeries, which require not only creating a craniotomy, but also cutting a flap in the dura. Complications during surgery can lead to disastrous consequences on health, including death. However, the cortical implant is applicable to almost all types of blindness.

Somatosensory Neuroprostheses

Given the importance of somatosensory feedback in motor control, the restoration of touch and proprioception is critical for upper-limb neuroprostheses to be clinically viable. To date, most efforts to restore touch through neural stimulation have focused on interfacing with the nerve or with the brain. The underlying principles are similar to those underlying visual and auditory neuroprostheses: Signals from transducers, in this case mechanical transducers on the prosthetic limb, are converted into patterns of electrical stimulation of neural tissue to elicit meaningful somatosensory sensations (**Figure 3**).

Figure 3 Pathway from M1 to S1 in a bidirectional BCI.

1. Peripheral interfaces

A few different interfaces have been developed for the nerve, some involving penetrating the nerve with electrode shanks (Branner and Normann, 2000), others flattening the nerve and stimulating it through its protective layers (Tyler and Durand, 2002), few others interfacing with the cell bodies in the dorsal root ganglia (Hokanson et al., 2011), and still others rerouting the nerve endings to intact skin and using tactors to stimulate them (Kuiken et al., 2007). The response properties of cutaneous mechanoreceptive afferents have been well characterized: indeed, models have been developed that can predict afferent responses to arbitrary spatial and temporal patterns of stimulation with millisecond accuracy (Dong et al., 2013; Kim et al., 2010, 2011). The relationship between afferent activation and perception has also been studied extensively. Indeed, the peripheral bases for form (Goodwin et al., 1997; Phillips and Johnson, 1981) and texture perception (Weber et al., 2013) have been characterized, as has that of perceived tactile intensity (Muniak et al., 2007) and pleasant touch (Löken et al., 2009). Furthermore, stimulation of individual afferents elicits very consistent and systematic tactile percepts that can readily be characterized by afferent type (Ochoa and Torebjörk, 1983). Thus, peripheral neural interfaces are supported by a strong empirical foundation. Naturalistic and well localized percepts have been achieved through stimulation of the peripheral nerve, both in acute preparations (Dhillon and Horch, 2005) and in chronic ones (Kuiken et al., 2007; Ledbetter et al., 2013; Raspopovic et al., 2014; Tyler and Durand, 2002).

2. Cortical interfaces

Wilder Penfield observed that stimulating the surface of primary somatosensory cortex elicits tactile percepts whose projected location on the body surface depended on where stimulation was applied (Rasmussen and Penfield, 1947). Romo and colleagues demonstrated that changing the parameters of intracortical microstimulation results in systematic changes in the evoked percepts (Romo et al., 1998). These early efforts laid the foundation for an approach to conveying somatosensory feedback, analogous to its visual counterpart, that consists in implanting arrays

of electrodes in primary somatosensory cortex (S1) and injecting small currents although these electrodes to elicit tactile and proprioceptive percepts (Berg et al., 2013; O'Doherty et al., 2011; O'Doherty et al., 2012; Tabot et al., 2013; Thomson et al., 2013; Venkatraman and Carmena, 2011). As is the case with their visual counterparts, the advantage of cortical over peripheral interfaces is that they are applicable to patients with upper spinal cord injuries. Stimulation through individual electrodes has been shown to elicit tactile percepts that are localized on the skin (Tabot et al., 2013). The perceptual magnitude of these percepts increases systematically and predictably with stimulation amplitude (Fridman et al., 2010; Tabot et al., 2013). While animals have been able to use this type of artificial sensory feedback to perform basic sensorimotor tasks (O'Doherty et al., 2011; Thomson et al., 2013), the intracortical approach is still in its infancy and has yet to be tested in humans.

Cognitive Neuroprostheses

Cognitive neuroprostheses aim to restore a cognitive function, such as attention, decision making, or memory. This approach typically consists of electrically stimulating the brain area that is thought to mediate the cognitive function in question. For instance, electrical stimulation of prefontal cortex in monkeys was shown to improve impaired decision making (Hampson et al., 2012), which might then pave the way to restore lost cognitive function in brain-damage patients. Among the prosthetics that have been approved by the FDA is deep-brain stimulation (DBS) that is described below.

Deep-Brain Stimulation

DBS is an FDA-approved procedure to treat movement disorders such as Parkinson's disease, dystonia, and essential tremor, but it may also be applicable to treat chronic depression and chronic pain (Young and Brechner, 1986; Anderson et al., 2012). In 1985, a patient suffering from essential tremor was to receive a thalamic ablation. Before the ablation, electrical stimulation was applied to determine the location of the tissue to be removed. When a specific portion of the thalamus was stimulated electrically, the tremor stopped immediately, which led the team, led by Benabid in Grenoble, France, to consider DBS as a treatment for motor disorders and paving the way for the first clinical trials of DBS in 1987 on a patient with Parkinson's disease (Benabid et al., 2009). More than 80 000 patients with Parkinson's disease have since been treated with DBS for pharmacologically intractable motor disorders. The surgical procedure for DBS is not without risk for the patient and can cause significant complications and side-effects such as mood changes or sensory/motor deficits. The site of stimulation depends on the type of disorder; the most common sites are subthalamic nucleus and globus pallidus for Parkinson's and dystonia, and the ventrointermediate nucleus for essential tremor. Stimulations of ventral posterolateral nucleus and of ventral posteromedial nucleus have been shown to alleviate pain due to cancer or due to phantom limb (Young and Brechner, 1986; Kringelbach et al., 2007). More recently, some evidence suggests that DBS could be used to treat chronic depression.

Vagus Nerve Stimulation

The vagus nerve, or 10th cranial nerve, regulates the heartbeat, controls some skeletal muscles, maintains breathing, mediates the transmission of a variety of chemicals through the body, maintains the digestive tract, contracts the muscles of the stomach and intestines to help process food, and conveys information about digestion and its metabolic consequences. Vagus nerve stimulation (VNS) is approved by the FDA to treat seizures (since 1997) and drug-resistant depression (since 2005). Similarly to DBS, VNS involves a pacemaker, implanted in the chest, which sends electrical impulses to the brainstem along the left vagus nerve. Because the right vagus nerve is involved in cardiac functions, stimulation of this structure could be fatal. The brainstem both relays and coordinates the information sent to several areas in the brain. Several groups (Sjögren et al., 2002; Clark et al., 1999; Groves and Brown, 2005) are investigating the possibility of extending VNS to treat Alzheimer's disease, chronic migraines, and tinnitus (a condition that affects hearing). VNS presents side-effects related to the laryngeal muscles. Several patients experience voice alteration, difficulty swallowing, throat pain, hoarseness, and coughing (Hsieh et al., 2008). Sleep apnea has also been reported in most patients (Marzec et al., 2003).

Efferent Neuroprostheses

In the first section, we discussed neuroprostheses that stimulate a tissue somewhere along the neuraxis. In another category of prostheses, information is read out of the nervous system to control an external effector. Measurements of neural responses can be split into two categories: invasive and noninvasive. The invasive techniques require a craniotomy and consist of measuring the activity of neurons by implanting electrodes at the surface of or into the brain. In these cases, either the responses of single neurons (single unit), of small groups of neurons (multiunit), or of large groups of neurons (electrocorticography or ECog) are recorded. Noninvasive techniques such as EEG or near-infrared spectroscopy (NIRS) can be used to measure the electrical activity at the surface of the scalp and thus do not require surgery. The choice between invasive or noninvasive technique depends on the application and on the targeted patient population. Noninvasive techniques may also be used in nonclinical applications but present the drawback of yielding a noisy signal.

Invasive Efferent Neuroprostheses

In an amputee or tetraplegic patient, the limb is either no longer there or no longer connected to the brain. However, the parts of the brain that sent signals to the muscles to move the limb are still functional. Signals from motor areas of the brain can be used to control an extracorporeal device, such as a prosthetic arm, or to stimulate populations of muscles to restore movement in the deafferented arm, an approach called functional electrical stimulation. The invasive version of this

approach consists in implanting multielectrode arrays in areas of the brain that are implicated in motor control, often primary motor cortex, as also premotor and parietal cortices. Then, the patient observes the movement of a prosthetic limb going through a series of motions, and is asked to imagine his or her own arm traversing those trajectories, while neuronal activity (in the form of single units, multiunits, or local field potentials) is recorded. Based on the recorded neuronal activity and the measured trajectories of the observed limb, a 'decoder' is built, which is a function that maps patterns of neuronal activity to kinematic states of the limb.

Algorithms to decode motor intention from neuronal signals have evolved rapidly over the past 15 years, from the one-dimensional control of a robotic arm used by rats to retrieve water droplets (Chapin et al., 1999), to two- (Serruya et al., 2002) and three- (Taylor et al., 2002) dimensional control of cursor movement by monkeys. Work with animal models paved the way for human experiments, where tetraplegic patients were able to control anthropomorphic robotic arms (Johannes et al., 2011) with many dimensions of control (Collinger et al., 2013; Hochberg et al., 2012). While these initial tests are remarkable and promising, many obstacles remain to be overcome to transfer this technology from the experimental laboratory to the home and to the clinic. For example, the chronically implanted electrode arrays have a relatively short life span (Judy, 2012) and thus would require periodic replacement, which is not an option given the dangerous surgery involved.

Noninvasive Efferent Neuroprostheses

In noninvasive efferent neuroprostheses, users modulate aspects of their brain activity, which are then used to control an external effector. Specifically, the signal is acquired and recorded in real time, features of interest are extracted (i.e., the aspects of brain activity that will drive the effector), and transmitted to an algorithm that converts these signals into a command to control a device such as a computer cursor or a robotic arm. Different types of brain features entail different types of control strategies (Zander et al., 2010), as detailed below.

Active BCI

In an active BCI, the signal is actively and explicitly controlled by the user. For example, the user might be explicitly instructed to imagine an action. Neuroimaging studies showed that imagining the movement activates similar areas in the motor and sensorimotor cortices as does performing the action (Jeannerod, 1997). Hence, this imagery-elicited signal can be used to control an external device. Signals that might be appropriate for an EEG-based BCI are sensorimotor μ and β rhythms. Indeed, when a user imagines a motor action, event-related desynchronization (ERD) decreases in the μ- (8–12 Hz) and β- (18–25 Hz) bands in the sensorimotor cortex; modulation in these bands can then be used to move a cursor (Pfurtscheller and Neuper, 2010; Brewster et al., 2014) or a prosthetic arm (Ramos-Murguialday et al., 2012; Gomez-Rodriguez et al., 2010).

Reactive BCI

In a reactive BCI, the neuronal activity evoked by repeated presentation of a stimulus is recorded. The subject is then asked to attend to one of the several stimuli presented, and algorithms are developed to identify the differential activity that is evoked by this target stimulus relative to that evoked by the other stimuli. Then, this differential activity can be used to decode a response from the subject, who then attends to one of the several stimuli to produce a response. In the decoding phase, the subject is presented with a set of interleaved stimuli. To produce a specific response, he or she must attend to its associated target. The cortical response to that target then shifts to an attended state, and the response associated with that target is recorded. In one approach, the P300, a positive deflection in the EEG signal that occurs at an average of 300 ms after stimulus onset, is used as a gauge of attention. The P300-based technique has been used to associate different targets with different letters, thereby allowing the subject to spell. This paradigm has been particularly useful in allowing patients with locked-in syndrome to communicate. An analogous approach consists in measuring the steady-state visually evoked potential (SSVEP). In this paradigm, the subject is presented with a visual stimulus that flickers at a constant frequency. The signal generated by the brain thus oscillates at the same frequency as the attended visual stimulus if the subject is attending to it. Thus, detecting the frequency present in the EEG can be used to determine to what stimulus a subject is attending to, and thus decoded as a response (in the same spirit as the P300 approach described above).

Passive BCI

Passive BCI extended the world of BCI to marketing, work environments, games, and human–computer interface. As indicated by its name, the user's brain activity is passive, which means that she is not asked to do anything. While she is going about some task that is unrelated to BCI control, like working on a computer, the BCI records and detects features from her brain activity that signal that she is stressed or that she may have made an error. If such an event occurs, the BCI then reduces the cognitive load imposed upon the user. A passive BCI record might then detect neural signatures of fatigue, arousal, working memory overload, or other cognitive or emotional states that might be triggered by the task. In one example of a passive BCI, participants were asked to navigate in virtual mazes with varying levels of difficulty (George et al., 2012). When the BCI detected a high mental load based on EEG signals, a haptic device was activated to guide the participant. Thus, the participant was doing the task unassisted unless his or her mental load reached a threshold, at which time assistance was provided. Using the same principle, some neuromarketing companies such as Neurofocus provide their clients with their consumers' physiological responses via a BCI while purchasing or being exposed to new products (Pradeep, 2010).

Conclusion

The development of neuroprosthetics has experienced exponential growth over the past two decades. Devices can be used to restore sensation, to control extracorporeal devices, to allow locked-in patients to communicate, and to monitor

physiological states to improve performance on a variety of tasks. Technologies range from highly invasive arrays of electrodes that are implanted in neural tissues to noninvasive devices that measure neuronal activity through the scalp. The promise of these technologies is only beginning to be realized, and it is difficult to imagine the state of the art of neuroprosthetics in 10 years.

Neuropsychological Testing

Abstract

This article examines the applications of neuropsychological assessment, with particular emphasis on some of the most common standardized batteries available for testing a wide array of functions. Some of the most widely used and empirically validated cognitive, behavioral, academic, and personality measures are discussed. The article concludes with a brief overview of how to summarize findings from a clinical evaluation in a comprehensive neuropsychological report.

Neuropsychological assessment provides psychologists with a powerful tool for understanding the cognitive and behavioral manifestations of underlying brain functioning. Clinical neuropsychologists administer assessments to clients in order to determine whether they are suffering from conditions that may not be readily detectable using brain-imaging technology, such as a learning disability or Attention-Deficit Hyperactivity Disorder (ADHD). Neuropsychological evaluations also enable psychologists to determine what kinds of services, or accommodations, may be most beneficial to the client. This article briefly explores some of the applications of neuropsychological assessment across a variety of contexts, examines widely used reliable and valid measures of cognitive functioning, academic functioning, behavior, and personality, and concludes with a suggested approach for summarizing assessment findings in the form of a comprehensive report, as well as a discussion on the future of standardized neuropsychological assessment in an era of rapidly developing technological advancements. Some of the most widely used assessments are described below, but it should be noted that the selected assessments discussed in this article are not an exhaustive list, nor is it possible to expound on each assessment's psychometric properties at length. The interested reader is encouraged to review the manuals associated with each assessment, which are cited within the text. Furthermore, neuropsychological assessments related to speech deficits are not covered in this article, and the interested reader is encouraged to reference other articles (*see* Language Disorders, Treatment and Remediation of; Classical Tests for Speech and Language Disorders).

Goals of Neuropsychological Assessment

Neuropsychological assessment has many practical applications; six important ones stand out: diagnosis; patient care; treatment planning and remediation; treatment evaluation; research; and forensic applications (Lezak et al., 2004).

The first goal of neuropsychology, diagnosis, may seem quite obvious. Although superior imaging techniques exist for identifying the sites of brain damage, a neuropsychological evaluation illuminates the extent of deficits related to that injury, and how they manifest behaviorally and cognitively. Moreover, sensitive diagnostic neuroimaging techniques do not yet exist for identifying certain organic brain disorders (e.g., ADHD), further necessitating the utilization of neuropsychological assessment.

Neuropsychological testing also provides clinicians and treatment providers with pertinent information relating to a patient's current level of functioning. For example, an assessment can provide insight into whether a patient is able to care for him or herself or whether the patient is capable of successful academic or professional performance. Relatedly, information concerning treatment planning can typically be gleaned from 'accommodations' provided in a neuropsychological report. In some cases, neuropsychological assessment may be useful in evaluating pre- and postadministration of pharmacological, medical, or surgical procedures.

Neuropsychological assessments can also be applied in research and forensic contexts. From a research standpoint, assessments are included in a wide array of research protocols, including those reporting slower processing speed abilities among soldiers with comorbid traumatic brain injury and posttraumatic stress (Nelson et al., 2009). Another recent study comparing neurocognitive functions among preterm and full-term children found that preterm children performed worse on neuropsychological measures of processing speed, certain aspects of attention and executive functioning, visual-motor coordination, as well as face processing and emotion regulation (Potharst et al., 2013). Neuropsychologists are also increasingly called to the courtroom to address issues in the legal arena, such as the possible consequences of traumatic brain injury on employment (Bigler and Brooks, 2009). In criminal cases, a neuropsychologist may be called to assess a defendant's mental capacity to stand trial or to explain how neuropsychological factors may help explain criminal behavior (Raine, 2013: pp. 309–310).

Clearly, this cursory overview of the applications of neuropsychological assessment does not do justice to the myriad ways in which neuropsychological assessments can help individuals with cognitive, intellectual, and physical impairments. The interested reader is encouraged to look at more comprehensive reviews of neuropsychological assessment; some suggestions are provided below.

Malingering

Before delving into a discussion of specific assessments, it is essential to understand how malingering may influence a neuropsychological assessment. Malingering is defined as the intentional generation of false or exaggerated symptoms, and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54049-5

can manifest in two primary ways: (1) deliberate exaggeration of symptoms that are difficult to measure and (2) intentional poor performance on psychological and neuropsychological tests (Iverson and Binder, 2000). Although malingering generally occurs in 'high-stakes' situations, including those in which individuals are suing for worker's compensation, are seeking a declaration of 'incompetence' to avoid standing trial, or are trying to plead insanity in a criminal case, psychologists should be cautious of this phenomenon when working with any patient. Individuals who are malingering may exaggerate memory loss, poor concentration, personality changes, or other bodily or cognitive symptoms. Clinicians should always assess malingering in the context of a neuropsychological assessment.

Psychologists have proposed several strategies for identifying malingering. Larrabee (2003) identified clinically atypical patterns of performance on five standardized psychological and neuropsychological assessments: Benton Visual Form Discrimination, Finger Tapping, WAIS-R Reliable Digit Span, Wisconsin Card Sorting Failure-to-Maintain Set, and the Lees-Haley Fake Bad Scale from the Minnesota Multiphasic Personality Inventory-2 (MMPI-2). Using the cut-offs established from his analyses, Larrabee was able to correctly identify 15 of 17 subjects meeting criteria for probable malingering. These findings suggest that examiners may be able to utilize built-in empirical methods for assessing malingering without having to administer additional assessments.

Selecting an Assessment Battery

Before selecting an assessment battery, it is first necessary to determine the purpose of the assessment. Specifically, the clinician should have a clear picture of the patient's referral questions, as well as an understanding of what the patient can gain from the assessment (e.g., a request for specific accommodations, such as additional time on a test to accommodate a slower processing speed). A patient being evaluated for possible ADHD will likely require a different test battery from someone who needs an assessment following a traumatic brain injury. An important benefit of neuropsychological testing is that it allows for the selection of tests that tap into specific cognitive functions, and more importantly, a test battery can be tailored to the individual needs of the client.

Mini Mental Status Exam

The Mini Mental Status Exam (MMSE; Folstein et al., 1975) is not a standardized neuropsychological assessment per se, but it is a very important feature of assessment that can oftentimes be used as a screening tool, most commonly as a screening test for dementia. This screener requires an individual to respond to questions in eight categories. The first category addresses orientation to time (e.g., year, day of the week) and the second addresses orientation to place (e.g., can the patient state where he or she is). Next, the patient's registration is assessed, which is his or her ability to repeat three randomly selected words. In order to assess attention and calculation, a neuropsychologist may ask a patient to spell 'world' backward or to count backward from 100 by 7's, i.e., 100…93…86…19…etc.

After some delay, the examiner will ask the patient to recall the three words he or she had asked him to repeat verbatim earlier during registration assessment. The examiner may also wish to assess the patient's language by asking him to name everyday objects (e.g., the examiner's pen). The patient may also be asked to repeat a phrase back to the examiner exactly as he or she says it. The examiner may then conclude the MMSE by asking the patient to carry out more complex commands (e.g., follow three-sequence series of directions, e.g., 'pick up the pen, fold the piece of paper, and give me the magazine').

Cognitive Assessments

Intelligence

The Wechsler scales are among the most reliable and widely used neuropsychological evaluations of intelligence. There are essentially three classes of this assessment: the Wechsler Intelligence Scale for Children, Fourth Edition (WISC-IV), which is administered to children aged 6 years, 0 months to 16 years, 11 months; Wechsler Adult Intelligence Scale, Fourth Edition (WAIS-IV), which is administered to individuals aged 16 years, 0 months to 90 years, 11 months; and an abbreviated version of these measures, the Wechsler Abbreviated Scale of Intelligence, now in its Second Edition (WASI-II), is available for individuals aged 6 years, 0 months to 90 years, 11 months.

The WAIS-IV and WISC-IV subtests are grouped into four indices or factors, and one global composite score, which is known as the Full Scale IQ (FSIQ). The four factors include Verbal Comprehension, Perceptual Reasoning, Working Memory, and Processing Speed. The Verbal Comprehension Index (VCI) taps verbal reasoning and knowledge of word meanings; the Perceptual Reasoning Index (PRI) taps spatial visualization, visual relationships, and nonverbal reasoning; the Working Memory Index (WMI) taps short-term auditory information and the ability to hold and manipulate information in memory; and the Processing Speed Index (PSI) assesses overall speed of information processing and the ability to screen out (ignore) irrelevant stimuli.

Both the WISC-IV and WAIS-IV have 10 subtests (although the specific subtests on each assessment vary, as will be discussed below); three subtests comprise the VCI, three subtests comprise the PRI, and two subtests each comprise the WMI and PSI. Additionally, on both the WAIS-IV and WISC-IV, the three verbal comprehension subtests and three perceptual reasoning subtests can be utilized in the calculation of the General Ability Index (GAI), which is useful when the FSIQ is uninterpretable. The FSIQ may be uninterpretable in cases where the difference between the highest Index and the lowest Index exceeds 1.5 standard deviations, or 23 points (Flanagan and Kaufman, 2009).

The three subtests that tap into the VCI on the WAIS are the similarities subtest, vocabulary subtest, and the information subtest. There is also a supplemental comprehension subtest. The three subtests that tap into the PRI are the block design subtest, matrix reasoning subtest, and the visual puzzles subtest. The two supplemental subtests that tap into this Index are the picture completion and figure weights subtests. The WMI is composed of two core subtests, digit span and

arithmetic, as well as one supplemental subtest, letter–number sequencing. The two subtests making up the PSI are symbol search and coding, with an optional cancellation subtest.

The organization and administration of the WISC-IV are very similar, but some of the individual subtests comprising the indices differ from the WAIS-IV. Three subtests comprise the VCI, including vocabulary, similarities, and comprehension, with optional information and word reasoning subtests.

The WASI-II is an abbreviated measure of intelligence, with options of administering two or four subtests to generate the FSIQ (Wechsler, 2011). The two-subtest form requires the administration of the vocabulary and matrix reasoning subtests, and only yields the FSIQ. The four-subtest form requires the examiner to administer the vocabulary, similarities, block design, and matrix reasoning subtests, and generates an FSIQ-4, a VCI score, and a PRI score. Whereas the WISC and WAIS each take anywhere between 60 and 90 min to administer to core battery, the WASI-II can take about 15 (2 subtests) to 30 min (4 subtests), thereby increasing efficiency in the clinical or research setting.

The Wechsler Preschool and Primary Scale of Intelligence, Fourth Edition (WPPSI-IV) is also available to test younger populations (2 years, 6 months to 7 years, 7 months), and provides similar information as the other Wechsler instruments. The 14 core, supplemental, and optional subtests combine to generate five Primary Index scales. These scales include a VCI, Visual Spatial Index (VSI), WMI, Fluid Reasoning Index (FRI), and PSI. An FSIQ is also calculated. The WPPSI-IV has adequate reliability, and improved normative sampling from previous editions. Furthermore, the age range was extended from 7 years, 3 months (which was the maximum age in previous versions of the WPPSI) to 7 years, 7 months in the present standardized version.

The Differential Abilities Scale, Second Edition (DAS-II; Elliott, 2007) is another cognitive assessment that is available for testing of children. The DAS-II provides scores reflecting verbal, nonverbal, and spatial abilities, as well as a composite measure of general cognitive ability (General Conceptual Ability score, GCA). The GCA is defined as the "general ability of an individual to perform complex mental processing that involves conceptualization and the transformation of information" (Elliott, 2007: p.17). In addition to the composite measure, two or three lower-level composite or cluster scores can also be calculated. These cluster scores vary by age. The DAS-II is divided into two batteries, an Early Years battery (2 years, 6 months to 6 years, 11 months) and a School-Age battery (7 years, 0 months to 17 years, 11 months).

The DAS-II has shown very good internal reliability, with subtest coefficients ranging from 0.74 to 0.96 across both the Early Years and School-Age batteries. Inter-rater reliability among subtests requiring examiner judgment (e.g., Copying, Recall of Designs) was high, ranging from 0.95 to 0.99. There is also evidence for the high internal validity of the DAS-II (Davis et al., 2012).

Executive Functioning

One common assessment of executive functions is the Delis–Kaplan Executive Function System (D-KEFS), compromising nine tests designed to tap into various verbal and nonverbal executive functions. Each of the nine subtests generates information about an individual's performance, eliminating the need for an overall composite score. In fact, one of the many strengths of the D-KEFS is that it provides great flexibility in administration because the examiner can choose only those specific subtests that will answer the assessment question; he or she does not have to administer a predetermined number of tests before obtaining a clinically significant index score (Delis et al., 2001).

The D-KEFS has been shown to have impressive test-retest reliability, as well as high internal consistency on the Trail Making Test, Verbal Fluency Test, and Color-Word Interference Test. The authors of the manual also explain that factor analytic studies aimed at deriving index scores were not necessary given that each test is designed to be a stand-alone measure. The D-KEFS can be administered across several developmental periods, from ages 8 through 89.

Sometimes, clinicians must diagnose neuropsychological functioning in younger individuals, and when this becomes the case, tests like the D-KEFS are not normed for these younger populations. As such, it may be necessary to use a test like A Developmental Neuropsychological Assessment, Second Edition (NEPSY-II) in order to test these younger populations. The NEPSY-II is available in two forms: one for 3- to 4-year-old patients (Preschool Age), and one for 5- through 16-year-old patients (School Age). The six functional domains of the NEPSY-II were derived theoretically rather than empirically. These six domains cover attention and executive functioning, language, memory and learning, sensorimotor, social perception, and visuospatial processing. Like the D-KEFS, the NEPSY-II is a very versatile assessment, with selection of subtests being based on the referral question. Subtests can provide an overview of neuropsychological functioning, a diagnostic measure specific to the referral question, a selective assessment to determine information about cognitive abilities, or the examiner can provide a comprehensive neuropsychological evaluation (D'Amato and Hartiage, 2008).

Memory Assessment

One of the best-known memory assessments in the field is the Wechsler Memory Scale, Fourth Edition (WMS-IV; 2009). This assessment comprises seven subtests that tap into five Index Scores: Auditory Memory, Visual Memory, Visual Working Memory, Immediate Memory, and Delayed Memory. The WMS-IV can be administered to adolescent and adult patients (16 years, 0 months through 90 years, 11 months).

The California Verbal Learning Test, Second Edition (CVLT-II; Delis et al., 2000) is another measure used to specifically evaluate verbal memory, and is available for adolescents and adults (16–89 years), as well as for children (5 years, 0 months through 16 years, 11 months). In both assessments, individuals are asked to recall a list immediately, after a delay, with interference, and with or without cues.

Another memory assessment that was uniquely designed for children is the Children's Memory Scale (CMS), which is normed for children aged 5–16. Unlike the CVLT-II, which is specific to verbal memory, the CMS assesses a broader range of memory dimensions, including attention and working memory,

recall and recognition, short-delay and long-delay memory, as well as both verbal and visual memory (Cohen, 1997).

Finally, the Test of Memory and Learning, Second Edition (TOMAL-2; Reynolds and Voress, 2007) is a comprehensive memory assessment available for children and adults (5 years, 0 months to 59 years, 11 months). The assessment consists of eight core subtests, six supplemental subtests, and two delayed recall tasks. These various subtests generate three core indices (Verbal Memory Index, Nonverbal Memory Index, and Composite Memory Index) and six supplemental indices (Verbal Delayed Recall Index, Learning Index, Attention and Concentration Index, Sequential Memory Index, Free Recall Index, and Associative Recall Index).

Motor Functions

The Finger Tapping Test (FTT; Reitan and Wolfson, 1993) is one of the most widely recognized tests of manual dexterity. Previous studies have found that measures of simple motor speed like the FFT are able to demonstrate more reliable differences between individuals with head injuries and those without than specific measures of memory or attention (Dikmen et al., 1995).

The Peabody Developmental Motor Scales, Second Edition (PDMS-2) assesses fine and gross motor skills among children from birth to 5 months. The PDMS assesses both quantitative and qualitative aspects of motor development among children. For example, an examiner qualitatively evaluates a child's grasp to determine whether the grasp is mature for the child's age. The length of time it takes for the child to grasp the cube is also recorded (quantitative measure). The developers of the PDMS assert that the quantitative information gathered during the assessment may be especially useful in developing remediation strategies. The six subtests of the PDMS assess various milestones of fine and gross motor development, including grasping, locomotion, object manipulation, body control and equilibrium, and visual motor integration (Folio and Fewell, 2000).

Academic Functioning

While academic problems and specific learning disabilities are typically assessed using structured psychoeducational batteries, it is not uncommon to also find psychoeducational measures in some neuropsychological batteries, depending on the reason for referral. For example, a child with sickle cell anemia may present with recent academic difficulties, including problems with attention and reading comprehension. Upon further medical examination, it is determined that this child has experienced a series of silent strokes, one of the many typical complications of his or her disorder. He or she is referred for a neuropsychological evaluation to determine the cognitive consequences of his or her strokes, but in order to obtain special accommodations at his or her school, the neuropsychologist may need to provide evidence that the cognitive impairments influence the academic concerns that were reported. In this case, using standardized measures of academic functioning may prove to be very useful in identifying specific areas of academic concern.

One well-known and widely used measure of academic functioning is the Woodcock–Johnson Tests of Achievement, Third Edition (WJ-III ACH; Woodcock et al., 2001). The Standard Battery includes 12 subtests that assess performance in areas such as reading, oral language, math, written language, and general academic skills. The different start points within each subtest are determined based on the individual's level of schooling rather than age.

The Wechsler Individual Achievement Test, Third Edition (WIAT-III) assesses reading, math, writing, and oral language in a total of 16 subtests. It is a useful tool for identifying academic strengths and weaknesses, and can inform an examiner's decision about the presence of a learning disability (Miller, 2012).

Specialized assessments of various academic subjects are also available, but a thorough discussion of their use and psychometric properties is beyond the scope of this article. Examples of these assessments would be found in the Key-Math3 (Connolly, 2007), the Gray Oral Reading Tests - Fifth Edition (Wiederholt and Bryant, 2012), the Clinical Evaluation of Language Fundamentals - Fourth Edition (Semel et al., 2003), and the Test of Written Language -Fourth Edition (Hammill and Larsen, 2009).

Personality Assessment

Similar to academic functioning, personality assessment is not necessarily a core feature of neuropsychological batteries. Nevertheless, in some cases, it may be necessary to assess an individual's personality in order to obtain a complete picture of present psychosocial functioning. Furthermore, as was discussed above, individual scales of certain personality assessments can be used to detect possible malingering, especially in 'high-stakes' assessment (e.g., assessing someone who would like to use the insanity defense).

There are a wide variety of personality assessment measures available; one way to distinguish these measures is to classify them as 'projective' or 'objective.' Projective measures allow an individual to respond to ambiguous stimuli, and it is thought that these responses may reveal important characteristics about an individual's hidden emotions. Some of the better known projective measures include the Rorschach Inkblot Test, the Thematic Apperception Test, and the Draw-A-Person Test. For the purposes of this article, emphasis will be placed on the 'objective' measures of personality, such as the MMPI-2 (Hathaway et al., 2009) and the Personality Assessment Inventory (PAI). Unlike the projective tests listed above, objective tests require the individual being examined to answer specific questions typically presented in a multiple-choice format. These responses are then compared to responses generated from the normative samples utilized in the creation of the assessment.

The MMPI-2 is a 567-item questionnaire that is composed of over 120 scales, 10 of which are the well-known 'clinical scales.' One of the many strengths of the MMPI is its use of validity indicators, which can be useful to detect threats to a valid administration, such as malingering, response inconsistency, and superlative self-presentation. The 10 clinical scales on the MMPI-2 are (1) hypochondriasis; (2) depression; (3) hysteria;

(4) psychopathic deviate; (5) masculinity/femininity; (6) paranoia; (7) psychasthenia; (8) schizophrenia; (9) hypomania; and (10) social introversion. On the clinical scales of the MMPI-2, a T-score of 65 is considered clinically significant, but these elevations should be interpreted in light of other psychosocial variables, which can typically be gleaned from a clinical interview with the participant. An adolescent version (MMPI-A) was also developed, and is currently one of the most commonly used assessments of personality among adolescents (Merrell, 2008).

The PAI provides an assessment of psychopathology in individuals aged 18–89. There are 344 items on this assessment, and together they make up 22 scales, including four validity scales, 11 clinical scales, five treatment scales, and two interpersonal scales. This measure has been found to have high internal consistency, convergent validity, and discriminant validity (Morey, 1991). An adolescent version (PAI-A) is also available.

Behavioral Assessment

Behavioral ratings can also be used to supplement formal neuropsychological assessments, but are not necessarily core features of a neuropsychological battery. Since a neuropsychologist only evaluates an individual for a few hours, it is difficult to obtain a clear picture of this individual's behavioral context outside the testing session. As a result, administration of behavior rating scales to the individual, caregivers, parents, and other important individuals with whom the client interacts can provide a wealth of information about possible problematic behaviors the client may be experiencing. In certain contexts, such as an evaluation of a possible ADHD diagnosis, behavioral rating scales are critical in ascertaining that the characteristic ADHD behaviors of impulsivity and/or inattention occur across several contexts.

While there are certainly several empirically validated rating forms available (e.g., Child Behavior Checklist, Behavior Assessment System for Children, etc.), this article will limit its discussion to the Behavior Rating Inventory of Executive Function (BRIEF), which can be used to supplement neuropsychological evaluations of impairments in executive functioning (Gioia et al., 1996). This questionnaire is available for parents and teachers of children aged 5–18. There are also adolescent self-report forms (BRIEF-SR), preschool age forms for children between the ages of 2 and 5 (BRIEF-P), and self and informant rating forms for adults ranging in age from 18 to 90 (BRIEF-A).

While the number of items on each of the versions of the BRIEF differs, the overall clinical scales tap into the same constructs, including working memory, emotional control, inhibition, and planning/organization. Overall, the BRIEF's good reliability, validity, and clinical utility make this a useful addition to any neuropsychological battery, especially where questions of cross-situational impairment may arise.

The Report

After evaluating a client, a neuropsychologist generally writes a report summarizing the referral questions, pertinent background information, data gathered from the neuropsychological testing sessions, an interpretation of the data, and formal recommendations and/or accommodations for the patient. After summarizing the referral question and reasons for the assessment, the neuropsychologist will then highlight relevant background history information. This section may include information about developmental milestones, medical history, academic history, employment history, and any significant injuries, hospitalizations, etc. The behavioral observation section of the report outlines information about the client's mood, affective state, as well as any observations that the clinician made about the client's performance, effort, and/or behavior across the different tests. Based on these observations, a clinician should include a statement reflecting whether he or she believes the results of the assessment are an accurate reflection of the client's current level of functioning. Next, the clinician generally presents the data gathered from the assessment batteries that were administered, explaining why certain assessments were selected, and what conclusions can be drawn about the individual's functioning across the various domains of functioning that were assessed.

After the data are thoroughly presented, the report typically concludes with a brief summary of the referral question, relevant background information, and a condensed overview of the findings. This portion of the report should emphasize the most important findings clearly and concisely so that it is apparent how the diagnostic impressions (which are listed after the summary) were determined. Finally, the clinician concludes the report with important accommodations and recommendations that the individual, his or her family, other professionals, etc. may find to be useful in treatment planning, academic planning, or judiciary proceedings.

Concluding Comments and Future Directions

Neuropsychological reports can be used in a variety of settings, and for a variety of purposes. Parents can use these reports to help their children obtain 504 plans or Individualized Educational Plans (IEPs). Neuropsychological reports can also be used in forensic settings to determine whether someone is mentally fit to stand trial or to help an individual obtain worker's compensation in a lawsuit. Because individuals rely on these reports for sometimes life-changing purposes, it is essential to obtain and maintain competence in assessment before administering, scoring, and interpreting a neuropsychological battery (American Psychological Association, 2010). Furthermore, the neuropsychologist should make every effort to meet with the patient, his or her family, or both in order to communicate the findings of the assessment, explain the recommendations and/or accommodations, and answer any questions the patient and his or her family may have.

Neuropsychological assessment can provide valuable insight into the current state of functioning of individual patients, and can enable a clinician to make recommendations about treatment and services that an individual may need to thrive in spite of having neuropsychological deficits. It is the authors' hope that this very brief introduction has introduced the reader to some of the more widely used neuropsychological

assessments, to their utility, and to their applicability across various domains.

All of the assessments listed above are generally administered using pencil, paper, and stimulus materials. Test developers have recently begun taking advantage of newer technologies to create standardized assessments that can be administered entirely on computers and tablets. Not only does the portability of standardized assessments increase administration efficiency, it also enables examiners to administer assessments in less time, and it simplifies the scoring process by having all necessary materials in one place (the tablet/computer). The CVLT-II is one example of a standardized measure that can now be administered in its entirety using this tablet-based system.

Abstract

Educational neuroscience attempts to coordinate evidence from behavioral and neuroimaging studies in order to obtain a more complete understanding of learning that can then be used to specify the pedagogical approaches and educational systems that will support it most effectively. The translational nature of this objective poses challenges because of its requirement for collaboration between researchers and educational practitioners. However, educational neuroscience research in literacy, number development, and science learning illustrates the potential of the field to explain both typical and atypical learning in a coherent fashion and to identify novel pedagogical strategies that fully address individual variation in capability.

Introduction: A Brief Conceptual History of Educational Neuroscience

Interest in the potential applicability of neuroscience to education stemmed initially from the wider growth of cognitive neuroscience – research on the relationship between brain function and cognitive activity – during the late twentieth century. As technology that had been developed in medical contexts became more refined and more readily accessible, new techniques emerged to support *in vivo* studies of neural activity. These made it possible to examine what happens at the brain level during mental processing of information and coordination of behavioral responses, such as those involved in carrying out numerical calculations. The use of functional magnetic resonance imaging (fMRI) – a method of measuring areas of increased blood flow in the brain and therefore, by inference, areas of greater neural activity – proved particularly successful as a means of mapping the apparent organization of brain function. Identification of recurrent regularities in the way in which neural activity is coordinated and deployed in different contexts led in turn to important reconceptualizations of the nature of cognition. The most striking example was recognition of the inadequacies of information-processing models derived from computing, which had been the guiding framework for cognitive psychology and cognitive science since the 1960s. In particular, it became evident that the brain does not engage in narrow sequential processing of items of information, but operates instead through large-scale parallel processing and the extraction of stable patterns, as, for example, in the learning and use of letter–sound relationships in reading.

The success of core forms of cognitive neuroscience led naturally to its extension to other forms of cognitive activity, including the perception and management of social situations (social cognitive neuroscience) and the processes by which adult patterns of neural activity emerge (developmental neuroscience). Again, both led to new insights, particularly with regard to the relationship between more primitive brain structures in evolutionary terms (e.g., the amygdala, which plays a central role in processing of emotion) and more uniquely human structures, such as the prefrontal cortex, which is involved in the manipulation of information and the control of other systems.

Given the fundamental role of the brain in learning, and the central concern of education with the organization and promotion of learning, it was inevitable that this further extension – which has gradually come to be called educational neuroscience – would be mooted as a possibility. Interest in the potential connection was further fuelled by perceptions of the inadequate and failing nature of educational systems in much of the developed world, and the growth of arguments in favor of evidence-based approaches to schooling that take into account the role of the brain in learning (Chipman, 1986). It was helped too by interest on the part of many educators – echoing wider popular fashion – in the powerful but apparently unpredictable influence of the brain on what they observed in their classrooms. Summing up these perceptions, the Royal Society (2011) concluded that the application of a scientific approach to learning based on neuroscience had the potential to bring about "a future in which educational practice can be transformed … just as medical practice was transformed by science about a century ago" (p. v).

As the Royal Society quotation makes plain, though, educational neuroscience never was, and never could be, the same kind of endeavor as social cognitive or developmental neuroscience. The latter are fields of research as traditionally conceived, operating within relatively well-defined and preexisting realms of enquiry, and with the primary objective solely of increasing understanding. The resulting knowledge may well have potential for application, but it is not typically an immediate concern of researchers working within these fields to consider those applications in planning their work.

Educational neuroscience differs in two fundamental ways. First, because education is a social invention, not a naturally occurring process (although it may have its roots in evolutionarily advantaged processes of intergenerational transmission of learning), educational neuroscience lacks any similar fixed realm of enquiry. While it can (and often does) focus on an analysis of the relationship between neural activity and learning within some current educational setting, like engineering, the object of such analysis is rarely understanding in itself, but the design of as yet unrealized approaches that will work in better fashion. It is therefore inherently an area of research in which consideration of application is a central concern. This focus on application gives rise to the second key

difference, which is that educational neuroscientists are necessarily driven to work at least part of the time in collaboration with those responsible for the design and delivery of education, rather than primarily as a community of researchers. Such collaboration is crucial for the identification of research priorities – those areas where existing education systems appear to have greatest difficulty – and for the design and trialing of workable solutions.

If collaboration of this kind is a necessary part of the field, it also carries substantial challenges, especially with respect to building sufficient shared understanding to enable effective communication and coordination of activity between the different parties involved. The difficulties have been recognized more or less since the beginning. In an influential early critique, Bruer (1997) argued that the endeavor was 'a bridge too far,' because the perceived connections between education and neuroscience were too remote, and were based too often on misunderstandings or overgeneralizations of one kind or another. One example he cited as an illustration was the claim – common at the time among educators – that the proliferation of new synaptic connections between brain cells (synaptogenesis) that takes place during infancy and early childhood represents a critical period for promoting enhanced learning in a variety of areas. Such claims were based on mistaken beliefs about the general nature of synaptogenesis and the functions it supports, beliefs that were based on limited contact with the relevant literature. The process is in fact focused to a large extent on specific regions of the brain and linked primarily to the emergence of basic perceptual and control functions. The learning of explicit procedures and content that are focal to education continues to be refined long after the early synaptic spurt has given way to pruning and consolidation of synaptic connections, which suggests that synaptogenesis has no real bearing on it.

Other forms of neuromyth, as these mistaken conceptions are commonly termed, still persist (e.g., left- and right-brain learning – most cognitive functions rest, in fact, on neural systems distributed throughout the brain). Other ideas that have taken root have more credibility but little systematic evidence in their favor (e.g., the value of training key functions like working memory – while training produces improvement on standard measures, there seem in fact to be substantial problems with transfer of these gains to classroom performance). The misunderstandings are not solely on the part of educators, though. Hruby (2012) details instances of the failure of researchers to engage with – or even respect – expertise regarding practice, which is essential if translational goals are to be met. Common failures include glossing over the conclusions of practice-based research, or attributing perspectives to practitioners that they do not in fact hold.

It is evident therefore that there are problems of translation and of contact in both directions, and that it is only by addressing these problems that, as Hruby contends, the real potential of educational neuroscience will become clear. Bruer (1997) argued that progress was more likely to be achieved via a series of discrete linkages, between educators and instructional psychologists, on the one hand, and between psychologists and neuroscientists, on the other. In the intervening period, some of these boundaries have become blurred: many educational researchers have acquired expertise in neuroscience methodologies, and better lines of communication have been established between teachers and researchers of different types. Precise prescriptions as to productive linkages are therefore probably outdated. Nevertheless, it remains plain that if educational neuroscience has any real future, it will not be driven by any single disciplinary agenda, but by wide collaboration between researchers from different backgrounds and practitioners of different types. It will also need support from government and policy makers because of the implications it carries for the nature of educational systems. In this article, I outline current thinking on what the objectives of educational neuroscience might be, what models of collaboration might work best for achieving these, and what existing evidence reveals about how far the endeavor might be worth the effort.

What Is Educational Neuroscience?

Although it has become widely accepted, the term 'educational neuroscience' is problematic because of what it implies – that it is concerned solely with attempting to explain education through neuroscience principles – and what becomes obscured as a result. While there is no very clear consensual definition of educational neuroscience, there is in fact general agreement that it is not reductionist, that it involves a range of methodologies, and that it is fundamentally concerned with the coordination of evidence of many different types, with neuroscience research providing just one strand.

The overriding objective is to obtain a more complete understanding of processes of learning, which can then be used to specify the pedagogical approaches and educational systems that are likely to support these most effectively. The past 20 years have seen growing recognition that single-level accounts of learning based on cognition, behavior, social process, or biological systems are necessarily incomplete: since all have evidence to support them, they must each be capturing part of a substantially more complex set of processes. It seems plain, then, that the way forward lies in attempting where possible to integrate evidence and accounts from different levels into a more coherent whole. As neuroscience research has uncovered influences and constraints on learning, it has become increasingly apparent that any attempt at integration must include the neural level if it is to offer any prospect of a complete picture. The contribution of educational neuroscience is to draw attention to this dimension – but not to the exclusion of other levels.

The model of the learner that emerges (see, e.g., Mareschal et al., 2013) takes the form of a multilevel system operating simultaneously at neural, cognitive, and social–environmental levels, with complex and multidirectional interactions between these. These result in unexpected – and even, to the practitioner, puzzling – constraints on progress, and substantial individual variation both in presentation during schooling and in educational outcomes. This variation is masked to some extent by equifinality – the achievement of ostensibly the same outcome via different routes. This gives a mistaken impression of the extent to which there is uniformity across learners and how far they can be catered to by one-to-many delivery within classes

using uniform approaches to teaching. In fact, as learners' backgrounds become more diverse, especially within urban centers of population, and the criteria for achievement become more exacting, any assumption of uniformity becomes increasingly problematic. What is needed is coordinated effort to (1) map and understand the cross-level interactions, seeking regularities and typologies wherever possible; (2) derive implications for practice that are sensitive to individual – and topic-to-topic – variation in what is likely to be effective; and (3) consider methods of translating these into actual practice, taking pragmatic constraints into account.

If these are the objectives of educational neuroscience, the implication is that it is better thought of not as an area of research in the same way as developmental psychology or cognitive science, but as a wider endeavor more akin to public health. The history of public health as a discipline and a practice provides some indication of what in fact the development of educational neuroscience may involve, as well as some clues as to the structures that may need to be evolved in order to achieve the translational objectives. The origin of modern public health is generally traced to the application of germ theory by John Snow during the 1854 cholera outbreak in London. His approach suggested that specific microorganisms were responsible for the spread of the disease, which led in turn to his identification of a polluted public water well as its source. This notable success helped overturn miasma theory – the notion that the origin of such diseases lay in airborne emanations from rotting organic matter – and resulted in a rapid extension of germ theory to a range of infectious diseases, a marked growth in public sanitation works, and over the ensuing decades the development of programs relating to public education (e.g., on infant health), vaccination, road safety, occupational safety, and drug control. Public health is now an established part of daily life in developed countries, and an explicit objective of developing ones due to the growth of governmental and international agencies promoting good practice (e.g., the US Surgeon-General's Office and the World Health Organization).

If the translational goals of educational neuroscience parallel those of public health science, then this implies that it should (1) concentrate attention initially on a few key areas of educational need where good theory can make an obvious difference; (2) build outward from these via core teams of individuals representing the different contributing strands of activity (i.e., the equivalent of epidemiologists, biostatisticians, local and national government officials, and health service professionals), whose activity is focused on mutually identified areas of need or risk and methods of counteracting these; (3) promote public knowledge of effective practices (without necessarily worrying overmuch about grasp of why these are important); and (4) let governments take control ultimately, while continuing to feed them good, relevant evidence. The key step in this sequence is almost certainly the second one, which depends on building a consensus across key players in multidisciplinary teams within different professional backgrounds, based on (within bounds) shared knowledge of the relevant science – while as far as possible avoiding bias toward any one approach that may undermine that consensus.

This is a complex and difficult balancing act. Researchers have a critical role to play in providing reliable and systematic evidence that can steer effective action. However, educational neuroscience research to date is piecemeal and unevenly developed. There is much work on dyslexia that is in fact already beginning to inform both remedial and mainstream teaching of literacy (see, e.g., Hulme and Snowling, 2009), but few other areas approach this level of activity, and some (e.g., conceptual growth in science, and gifted and talented children) have so far been addressed by only a handful of researchers. Moreover, there is no unifying framework of the kind provided by germ theory; to the extent that there is a consensus across researchers, this is based on a shared belief that a full understanding of learning processes demands consideration of the neural level, but not what form the resulting models should take. A bigger picture is unlikely to emerge without a more coordinated program of research, covering typical and atypical learning in key areas, especially language and literacy, number and mathematics, and conceptual development and causal understanding in science, widely regarded as the three most important areas of the school curriculum and the principal focus of comparative international assessments.

Equally important is the need to progress as a community in a number of different senses. One aspect of this is researchers from different disciplinary backgrounds working as equal partners. However, researchers can only be one part of a wider community of engagement and exchange that helps set the research agenda and maintains a focus on the implications for practice, including delivery. This wider community also needs to encompass teachers, trainee teachers, teacher-training agencies, educational psychologists, speech and language therapists, pediatric neurologists, and members of other professions involved in implementing evidence-based support for learning and remediation of learning difficulties. If the public health analogy is taken seriously, the function of this wider community extends far beyond a consultative role: it needs to be an active partnership of researchers and professionals working together to identify issues, improve understanding through rigorous research, and develop solutions. Practitioners will therefore need to be involved at the heart of the research, and researchers will need to engage with issues of delivery. These roles are at present largely unfamiliar to all concerned and mostly lack any obvious institutional support. Any functioning team therefore demands an unusual commitment on the part of its members, based primarily on belief in the potential of the work rather than substantial concrete evidence of benefit.

This last point suggests that there also needs to be engagement with policy makers and policy shapers, in order to help ensure that educational neuroscience has socially perceived value, and that team members are positively sanctioned to contribute to the development and deployment of novel forms of provision. Given an environment within which politicians and policy specialists are subjected to constant streams of lobbying by organizations with competing vested interests, success on this front will depend on standing out in some way – hence the importance of good science and convincing applications based upon it. If this was true for public health science, it is even more so now.

Do We Really Need Educational Neuroscience?

Given the complexities involved, is educational neuroscience as an endeavor actually worth the effort? I will address this question by briefly considering work in the three key areas identified in Section What is Educational Neuroscience?: literacy development, number and mathematics, and science learning.

Literacy Development

Learning to decode written forms of language rests in fundamental ways on the child's earlier acquisition of oral language, especially where the orthography involved is alphabetic in character. Even where children grow up with a character-based orthography such as Chinese, initial language acquisition provides them with an implicit sense of the organization of the language. This includes the division of sounds into meaningful word units or morphemes, the basic vocabulary encoded in this way, and acceptable ways of putting this into sequences to create extended meaning – the grammar of the language. There is good evidence that children have an innate sensitivity to these characteristics as they manifest in their local language community, and that imitative observational learning plays an important role in acquiring use of them.

This prior knowledge provides the child with a valuable tool in the more deliberate – and instructed – process of learning to read, since it makes it possible to map the orthographic forms that they encounter onto known elements of language. Initially, at least, this mapping happens at the whole-word level and in rote fashion (what Hulme and Snowling, 2009, call the prealphabetic stage), with children simply learning the association between a given written symbol or set of symbols and a spoken word or morpheme that is significant to them. Rote learning of this kind is inefficient, however, and where the language uses alphabetic orthography, a further level of mapping is possible at the grapheme–phoneme (i.e., letter–sound) level. Guidance on these correspondences helps the child to begin to decode writing into known words without needing the assistance of others to tell them what each word is.

As soon as children have begun to acquire basic letter–sound and letter–name knowledge, they use this mapping to learn the relationship between letter strings and their pronunciation (the alphabetic stage). At first, they are better able to work with larger units than single letters and phonemes, with syllables ('crust') and onset–rime structures ('cr' and 'ust') marking important points of transition to the use of full phonological strategies, in which letters are sounded out and blended to arrive at the pronunciation of unknown words. Finally, as these strategies become more familiar, they become more automated, so that sounding out is no longer necessary. At this point, the child starts to extract the spelling rules that they encounter (the orthographic stage) and in a sense return to whole-word recognition – but on the basis of explicit knowledge about word composition and strategies for decoding unknown words.

Phonological awareness – the ability to identify sound values in speech and to decompose spoken words into these – is a key precursor of learning to read, since it underpins the shift to the alphabetic stage, and makes it possible to bind orthography into preexisting neurocognitive structures that link phonology and meaning. There has therefore been a gradual shift (in the United Kingdom, at least) toward the use of phonics teaching for reading in elementary schools. This involves working directly in the early years to promote awareness of phonemes. However, in English, this approach needs to be accompanied by work on whole-word recognition for high-frequency words because of the number of irregular spellings, which limit the value of grapheme–phoneme conversion as a method of learning to read. Children need to recognize where these mappings do not apply and words are not pronounced as they are written (e.g., 'yacht').

Neuroscience studies using fMRI have identified the neural pathways involved in reading and the anomalies found in children with dyslexia (Demonet et al., 2004). These studies reveal that the main problem is a deficit in the emergence of phonological awareness. Although there are competing theories about the nature of this deficit, the key step in learning to read efficiently appears to be the development of amodal processing structures in the temporoparietal and left ventral cortex, which integrate phonology, orthography, and semantics within what is known as the verbal word form area (VWFA). Metaphonological awareness – the capacity to deliberately utilize knowledge of word sounds – is strongly implicated in the building of these structures. This work has also demonstrated that the differences that separate nonimpaired from impaired readers also predict individual differences in typically developing children, implying that dyslexia is not a qualitatively different syndrome but a more pronounced degree of deficit. This appears to be marked by especially poor neural connectivity in the VWFA and anomalies in the profile of neurotransmitters, the chemical messengers that carry activation from neuron to neuron. It is important to note that how far this deficit has an impact is also affected by the nature of the letter–sound relationship in the child's native language. Reading disorders are less apparent where there is a consistent relationship between letters and phonemes, such as in Spanish or German, or in writing systems that do not require segmentation into phonemes, such as Chinese or Japanese. This suggests that the crucial dimension is sensitivity to complexity in orthographic mapping onto phonology.

Computer modeling of brainlike processing structures also highlights the importance of regularity in determining how difficult it is to build up stable representations of letter–sound relationships (Harm et al., 2003). Such modeling has been able to explore how the underlying deficit might be corrected in an irregular language such as English, as well as identify the stage at which remediation of different sorts is likely to be successful (Ziegler et al., 2007). This has led to the development of phoneme practice as a form of remediation, and evaluation of the brain activation changes in children who respond positively compared to those who do not. This work indicates that normalization is achievable in the majority of cases. Studies using electroencephalography (EEG) measures of electrical activity in the brain have also made it possible to identify children at risk of dyslexia before they begin to learn to read (Lyytinen et al., 2001), so that remediation can begin at an early age. Similarly, while it has long been known that reading difficulties tend to run in families, candidate genes that may affect brain development have now been found

(Schulte-Körne et al., 2007). Such understanding makes it possible to contemplate yet earlier forms of remediation.

Number and Mathematics

As with reading, it is the earlier stages of mathematics learning that are best understood. The focus of most research has been on the growth of children's understanding of number and arithmetic (the concrete use of number within the basic operations of addition, subtraction, multiplication, and division) in the preschool and elementary school years, since (as with word reading) this basic level underpins later achievement.

There is good evidence that infants (in common with other primates) possess two innate perceptual systems for recognizing number. One system enables them to distinguish, without counting, small exact quantities up to 3 – what is termed subitization. The other allows them to judge relative differences in large quantities (e.g., 16 vs 32) (Xu and Spelke, 2000). These systems have been argued to provide a foundation for the acquisition of verbal counting skills in the same way that phonological awareness provides a start point for reading. The linkage between perception of number and counting may be less exact, however, since children have to grasp new principles that apply only to the latter (Gelman and Gallistel, 1978). These include the one-to-one principle (each object to be counted only gets one count word), the stable-order principle (count words get used in fixed order), the order irrelevance principle (the order in which objects are counted makes no difference to the total), and the cardinality principle (the last count word used represents the total number of things in the set). Current evidence suggests that grasp of these principles is relatively hard-won on the basis of prolonged practice and that children move more easily from the innate systems to estimation (Gilmore et al., 2007).

Basic counting ability is usually in place by the time children go to school, and it forms the foundation for the growth of arithmetic skills (Hulme and Snowling, 2009). However, these skills are more disparate than those involved in reading, and they include single- and then multiple-digit addition, subtraction, multiplication, and division, along with varying strategies for carrying out these computations; understanding of tens and units, and the role of place value in distinguishing between these; translation between arithmetical problems presented in concrete, verbal, and numerical formats; knowledge of number facts (e.g., any number multiplied by 10 is equal to the original number shifted one place leftward with a 0 on the end); and derived fact strategies (e.g., use of the multiplication by 10 fact to decompose sums into workable subproblems).

There appears to be no consistent order for the emergence of these components, or any particularly strong relationship between them as they are acquired (Dowker and Sigley, 2010), so children may show surprising gaps and a wide range of individual variation. Dyscalculia, a basic deficit in the ability to learn arithmetic, was identified over 30 years ago, but the research on inherited number awareness has led to recent developments in understanding. The neural pathways involved in typical numerical capacities are now relatively well understood (Castelli et al., 2006), and dyscalculia appears to be due to a deficit in this number awareness associated with functional and structural abnormalities in a region of the parietal lobe known to be specialized for enumeration. This is reflected in poor performance on tasks such as saying how many dots there are in a visual display, or comparing two displays to say which has more (Landerl et al., 2004). Less is known as yet about the precise nature of this deficit than is the case for dyslexia, but research has led to interventions that are aimed at strengthening number sense via practice with the kinds of displays used to diagnose problems (Butterworth and Yeo, 2004). These appear to be more effective than more traditional interventions for children with number problems, which focus on simple repetition of number–object correspondences: it is not counting as such that is the source of the problem.

However, the relationship between arithmetical skills and innate abilities appears to be weaker than it is for reading. Achievement in arithmetic has been found to be more strongly and consistently related to knowledge of number facts and working memory ability (Cowan et al., 2009; Soltesz et al., 2010). Given the role of attention and executive control in counting and computation, and the way in which knowledge impacts the strategies used for solving problems, this is unsurprising. It does, however, make it harder to tell as yet what kinds of teaching strategies might be most effective, especially for learners with less distinct deficits.

Science Learning

As with reading and number, the cognitive capacities on which science understanding depends originate in the preschool period, and again key aspects appear to be innate. There are three elements of learning in science: factual knowledge (evidence), grasp of scientific procedure (generation of evidence), and conceptual grasp (understanding of phenomena). Despite the emphasis in much teaching on the first, and in research on the development of scientific thinking on the second, it is concepts that are central, especially during elementary school, since they provide unifying ideas about causal processes that help learners make sense of subsequent experience. These are essentially the ideas or theories that eventually provide the basis for meaningful scientific testing, and they therefore need to be put in place first.

There is good evidence that infants have an innate sensitivity to causal information, so that, for example, when one object strikes another and the second object moves, this is naturally perceived as the first object causing the second to move (Gopnik et al., 2004). Neuroscience evidence supports this claim, indicating a brain basis for the organization of causal perceptions (Satpute et al., 2005). By 2 years of age, children are capable of employing retrospective assessment of patterns of association between cause and outcome in order to anticipate the consequences of a specific event, and they do so with considerable statistical accuracy (Schulz et al., 2007).

However, this early understanding is not the resource for subsequent science learning that it has the potential to be.

While innately organized perceptions may provide a starting point, they are based on implicit sensitivity to covariation between events, and are not automatically verbally accessible. They are therefore not the same as explicit concepts, which can be broken down into elements that can be described in language and subjected to analysis and discussion. Explicit concepts appear typically to have a distinct point of initial origin in conversations around everyday experiences, and to relate to causal perceptions in at best a distorted and piecemeal fashion that is resistant to change (Howe et al., 2012). EEG studies with adults reveal separate neural activations associated with accurate implicit perceptions and inaccurate explicit concepts (Kallai and Reiner, 2010), indicating that failure to integrate the two is a commonplace outcome.

As with number, then, the crucial educational step is the accurate mapping of explicit concepts onto implicit perceptions and the consequent calibration between observable regularities and inferred causal relationships. However, this mapping appears to be constrained in a number of ways. In adults, fMRI studies show that coordination of incoming observational data with preexisting concepts is strongly associated with activity in the dorsolateral prefrontal cortex, a region linked with working memory and executive function (Fugelsang and Dunbar, 2005). Deliberate executive control is known to be relatively late maturing (Zelazo et al., 2008), suggesting that before the age of 10, sheer management of cognitive load may substantially limit implicit–explicit mapping. Although direct evidence is as yet scant, it also seems likely that individual variation in attentional and working memory abilities further impacts the pickup and coordination of perceptual information. There may even be yet-to-be-recognized dyscalculic-like deficits in sensitivity that impose additional constraints for some learners. At the other end of the mapping process, there is clear evidence of the importance for conceptual progression of learners being externally resourced with explicit vocabulary and explanatory constructs for encoding and manipulating concepts, and experiencing events within which language and observation are brought together (Philips and Tolmie, 2007). Both types of experience vary from individual to individual to a far greater extent than exposure to count words and counting experiences.

In terms of educational approaches, this analysis suggests that it is important that elementary school teachers provide children with concrete experiences that (1) involve manipulation of causal events, (2) draw attention to the exact sequence within these (e.g., what happens when an object that barely floats is dropped into a tank of water?), (3) provide descriptions to help make this sequence explicit, and (4) connect these descriptions to explanatory constructs. In fact, cooperative group work in science typically embodies all of these features and has been shown to produce robust improvements in conceptual understanding (Tolmie et al., 2010). Its success has generally been attributed to its capacity to generate explanatory dialogue, however. The educational neuroscience approach suggests that the combination of observation and dialogue is in fact more critical, and that the group context may further assist learning by establishing a setting in which there is good reason to explicitly refer to observations and where the informational load is made more manageable by distributing it between individuals.

Implications

Section Do We Really Need Educational Neuroscience? illustrates that educational neuroscience is indeed capable of making a distinctive contribution both to our understanding of key areas of learning and to the development of evidence-based pedagogical practices that will improve outcomes for typical and atypical learners. Although I have focused on literacy development and number and science learning, it is important to note that the range of relevant work is considerably wider. For instance, there is a growing body of research on socio-emotional development from infancy through adolescence, and how this is impacted by the organization and refinement of neural structures relating to processing of facial information, mentalizing (the attribution of mental states to others), and sensitivity to acceptance and rejection by others (Blakemore et al., 2013). The key nature of later refinements in particular argues that forms of social education have a potential importance in high school curricula that is presently largely unrecognized. Another strand of this research has helped identify abnormalities in the amygdala that are associated with impaired emotional awareness and callous-unemotional forms of antisocial behavior, suggesting alternative approaches to educational intervention with the most intransigent disruptive students (Jones et al., 2009). Research in the area of second-language learning has repeatedly demonstrated an important predictive role for low-level sensitivity to perceptual regularities in the language being learned (Frost et al., 2013), underscoring the importance of immersive pedagogies. Other pertinent work concerns shifts in adolescent sleep patterns and their implications for the timing of the school day (Lockley and Foster, 2012) and the development of attention and executive function (de Haan, 2013).

Across these different areas, the best work rests on a combination of behavioral and neuroscience methodologies, including both direct brain imaging and computational modeling. At present, effective interventions are based largely on behavioral work (much of this drawing on teacher expertise in its inception). However, by combining this with neuroscience, we are beginning to be able to explain better why these work and to build models of individual variation at a level of sensitivity that behavioral studies alone are not able to achieve (Thomas, 2013). In time, it is likely that wholly novel interventions that address this level of detail will begin to emerge.

There are other important implications, however. First, it is apparent that literacy, number, and science learning call upon a relatively unique constellation of functions and processes, with even the types of implicit–explicit mapping involved in each being distinctive in character. This may mean that there are likely to be few general principles underpinning successful learning across different areas. We need to keep looking for such principles as they may be beyond current conception, and more coordinated research activity is crucial for this reason. Even then, research in each area will probably remain at best only loosely interconnected for the immediate future.

The key objective at this stage is to map the skills necessary to progress in focal areas of the curriculum, the main steps involved in developing these, and the types of clinical and

nonclinical variations that can arise. These mappings can then be used to derive evidence-based strategies for promoting learning in each area and managing individual variability. There is a particular need for greater emphasis on mainstream development in order to extend the potential benefits of educational neuroscience to broad populations, rather than just those with specific deficits.

These points also mean that there are unlikely to be any effective overarching pedagogies – if different areas of education rest on different functions and skills, these will typically require different specific methods of support, and these may in turn differ according to individual need. The training of teachers and provision for support of their continuing development will therefore need to shift emphasis to promoting understanding of the range of evidence-based models that are applicable to their working context, placing them in a position somewhat akin to that of a medical general practitioner. This is a radical change, and given the scale of the new knowledge to be understood and deployed, it may entail a further need to strike a different balance between school-based and out-of-school education, with the former concentrating on provision of finely honed development of key skills, which are then elaborated according to personal choice in a diverse range of other settings. This pattern already exists to some extent, and it shows signs of accelerating. This in turn suggests a need for governments and wider society to come to a more explicit consensus on what the objectives of education should be, and how far to embrace (and resource) the evidence-based approach at the core of educational neuroscience.

Neurosociology

David D Franks, Virginia Commonwealth University, Richmond, VA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article begins with a description of neurosociology, its basic unit of analysis, and how the name was coined. This is followed by generalizations about the brain – its complexity, its disadvantages, and how emotion organizes it. After placing the brain in evolutionary perspective, the concept of emergence is used to address the mind/body problem. The importance of the 'new' unconscious is discussed and Damasio's finding that emotion is necessary for rational decision making is detailed. Other subjects include consciousness and how the same things feel different to people. The mind and how it changes the brain is a current topic in neuroscience, and mirror neurons show how we are joined socially.

What Is Neurosociology?

Neurosociology is the study of the social nature of our brains as they developed through evolution because human intergroup cooperation had significant survival value. According to neuroscientist Leslie Brothers (1997), "We take the first step by acknowledging that the network of meanings we call culture arises from the joint activities of human brains…it (mind) cannot be derived from any one brain in isolation." What brings this further in line with sociological social psychology is her statement (1997: p. 39) that "While our individual brains are singular and self-contained, the processes on which they depend for functioning are social ones…there is no fully working brain without other brains."

The usefulness of neurosociology to its parent field of sociology can be seen partly as clarifying previous misunderstandings about biology. Sociology grew up in a time of clear divisions between nature and nurture. It defined itself as being opposed to natural instinct and insisted that there were as many human natures as there were cultures. Neurosociology shows clearly that we have a human nature and that it is social, however impressive the cultural variety of *Homo sapiens* may be. This means, as argued by scholars such as de Waal (2009), that the extreme individualism of our westernized culture, and more specifically our economy, is not tailored to our social natures and can be self-destructive, as events such as the Enron collapse (de Waal, 2009: p. 39) and our present economic predicaments demonstrate.

There was a time when sociologists were very critical of another area of biology – genetics. Rather than making either/or assertions about the effect of genes on human behavior, we now seek understanding in the interactions of genes and physical and social environments. A gene without experience in an environment is not a working gene. Even morality is seen to have a brain-based foundation that is part and parcel of social life.

For example, Gazzaniga argues that the human brain is by nature moralistic and that cross-cultural morals derive from the very social capacities that helped *H. sapiens* survive in the early days of our evolution. Churchland (2011: p. 59) also sees social and moral behaviors as parts of a single continuum. She notes that the same regions of the prefrontal cortex increase in activity whether the subject witnesses a purely social event or a clearly moral one.

Universal ethical issues focus on what types of killing are defined as murder and what forms of sexual intercourse are incestuous, what constitutes lies, and what it means to break promises.

Brothers and others point to the many social tendencies that infants have wired into their brains at birth (1997: pp. 12–13). She cites a study of 40 infants with a median age of a mere 9 min old who are more likely to turn their heads and eyes to an upright picture of a face rather than to an upside-down one, a scrambled one, or a blank one. She points to other studies showing that 7- to 11-week-old babies had a slight tendency to attend to the region of the eyes when a person was talking rather than to the constantly moving mouth. This should draw the most frequent attention, but it was the emotionally expressive eyes that drew interest.

> There is no question, Brothers argues, that when infants are simply fed by a bottle and are without other social and affective interactions, they do not develop emotionally. Because emotion is a critical organizer of the brain, they do not develop cognitively and become depressed and anxious. Such infants do not develop interest in, or even a capacity for, social activity. In its place is fear, anxiety, and depression and in many cases ordinary infant diseases lead to death. Tredway et al. (1999) have shown the specific brain processes that make this happen.

These examples provide important correctives to sociology while strengthening greatly the evidence of the profound degree of our social natures.

A History of the Name and Neurosociology's Basic Unit of Analysis

As early as 1972 Joseph Bogan, who was instrumental in the first split-brain research, and sociologist Warren TenHouten (2013) used the term neurosociology. The next year TenHouten and Charles Kaplan published the first sociologically oriented monograph dealing with neuroscience, *Science and its Mirror Image*. A significant number of sociologists began to think past E.O. Wilson's reductionist version of sociobiology and there was enough neurosociological work for Franks and Smith to edit *Mind, Brains and Society: Toward a Neurosociology*. In 1992, cognitive psychologists Cacioppo and Bernston used the term social

neuroscience to describe their entry into the social aspects of the brain.

The basic unit of analysis for neurosociology must be interactional, including at least two actors, whereas social neuroscience is not as constrained.

Theodore Kemper has referred to academia's 'fortress mentality,' wherein sociology and psychology are seen as being at odds with each other, but in brain science such a stance is counterproductive, and there is much we can learn from cognitive psychologists, especially those working in embodiment.

Important Things to Know about the Human Brain

Complexity

Edelman says that the cerebral cortex, covering only two-thirds of the brain's mass, contains at least 30 billion neurons, with 1 million billion associated connections or synapses. (A single neuron is merely a piece of meat; it requires other neurons to make a functioning neuron.) Thus, it is the synapses that matter. Counting one connection a second, it would take 32 My to count them all. This includes only the brain's neocortex, 80% of the brain. Eagleman (2012) writes that "there are as many synapses in a single centimeter of brain tissue as there are stars in the Milky Way Galaxy. Each of these cells is as complicated as a city."

According to Brothers, comprehending such complexity will have to be facilitated by a unifying theoretical framework specific to the complex workings of the brain. Examples of this kind of theory are "an atomic theory of matter, the germ theory of disease, a genetic theory of inheritance…a natural selection theory of evolution…" (Brothers, 2001: p. 67).

The Limitations of the Brain

The brain is not built to solve all the problems that experience brings to us. Perception is selective and memory is riddled with falsehoods. This lack of perfection – or even approximations of it – occurs because the brain is a 'tinkerer.' It can build only on brain structures that its past development have made possible. For example, the brain-circuits supporting consciousness were very small in our evolutionary past and had to borrow from and in some sense deplete circuits that existed next to them. We make a serious mistake when we see the 'higher' and newer prefrontal lobes as developing separately from the deeper limbic emotional system. The new works minimize and constrain the old, and the old works raise and influence the new.

The Brain as Relational

The brain is not sufficient unto itself. A functioning brain needs a social and physical environment. Persons placed in sensory deprivation tanks for extended periods of time have hallucinations and can have a number of distressing symptoms. Brain cells die if they are not used to act on the world in daily life and relations. "Use it or lose it" is not just a cliché. Children whose temper tantrums go unchecked simply do not develop the neuronal pathways from the prefrontal cortex going down to the emotional limbic system needed to control themselves. This problem is augmented by the fact that circuits going upward from the limbic system to the prefrontal cortex are much more robust than those going down.

Projection

Neuroscience has shown that any epistemology assuming that our brain-driven minds somehow passively copy what is 'out there' is misguided. This includes analytical philosophy, any kind of correspondence theory, and Locke's British empiricism, wherein experience 'writes itself' on the mind, which he conceived as a 'tabula rasa.' Our brains determine as much of what we observe as do the objects themselves. This is because our senses are transducers. Transducers take energy from one system and change it into a different form that will accommodate that system. The human eye takes light waves or amounts of electromagnetic energy and transforms these waves into what we experience as color. Without ears, there are compressions of air, but it takes an ear and a brain to make noise. True, stimuli are initiated independent of our will and in this sense there is an objective world, but how it is experienced depends on the brain/world interaction. According to Buckminster Fuller, what we can sense is less than a millionth of what is 'out there.' Various animals truly live in different worlds.

In sum, the brain selects, edits, and changes stimuli into what it can accommodate. It sees patterns where there are none, and much of the brain is constructed to receive only the gist of things.

The Brain Is Divided into Two Different Halves

Roger Sperry (1965) discovered that the two halves of the human brain were complementary to each other. The left side was logical, conscious, and speech driven. The right side was given to gestalts and 'getting the gist of things.' Sperry and his student Michael Gazzaniga treated epilepsy patients by severing the corpus callosum, which allows communication between the right- and left-brain hemispheres. The corpus callosum is a massive cable of 200 million fibers enabling the fully linguistic left-brain (in right-handed people) to know what the characteristically nonlinguistic right brain is doing. The mute right brain communicates by electrochemical means. Sensory information from the patient's left side is processed by the right side of the brain and vice versa.

After such severing, the right side can no longer tell the conscious left side what it is doing. Thus, a patient can be given a written message flashed to the right side of his face instructing him to draw a dog. But the severed corpus callosum prevents this communication to the conscious left hemisphere. This leaves one person with two brains, one of which is ignorant of the other. Patients had no clue about what they were drawing until its form becomes obvious during the sketching. Only then will they realize they are drawing a cat or dog, etc. When the right brain is asked why the patient drew it, the left, usually 'linguistic brain,' contrives an answer that makes some sense to the patient (who is the only one deceived). In another case, patients' right brains were asked to laugh and then they were

asked what was so funny. The patients never said they did not know why they were laughing. A reason was always forthcoming that only the patients themselves could believe because the researchers knew they were actually only following their directives for the research.

In other places I have argued that this provides evidence for notion of 'accounts.' What sociologists refer to as vocabularies, motive neuroscientists call confabulations.

Measures

If the human brain is imperfect, the measures we have for it are imperfect as well. There are a number of tests currently available and in wide use. The CAT scan uses X-rays taken from various angles, and they are often combined to produce three-dimensional (3D) images. The letters CAT stand for computerized axial tomography; PET stands for positron emission tomography. Small doses of radioactive traces are absorbed by the body part in question via the veins. The tracer substance releases energy, which is converted into 3D images. One advantage of PET scans is that only minimal doses of dangerous radiation are required, but the high cost of the short-lived radiation and the procedures to synthesize them before they decay mean that many hospitals cannot afford the equipment, making scheduling of the tests difficult.

Magnetic resonance image (MRI) measures give still pictures of brain structure. MRIs are used to correlate structural brain changes or differences in behavior.

Functional magnetic resonance images (fMRIs) give noninvasive 'movies,' or pictures of brain functioning, whereas MRI measures give only still pictures of brain structure. What is really measured is the oxygen levels in the brain. When neurons fire they take up oxygen, and this process is what is measured. fMRIs use a software program called the BOLD (blood-oxygen-level dependence) technique to measure the ratio of oxygenated to deoxygenated hemoglobin in the bloodstream; this simply correlates with neuronal processes in certain areas. It does not take direct single measures of neurons. Compared to other electrophysiological techniques, fMRIs have significant limitations, creating the need for extensive post-test processing. Published results are often averaged over time and smoothed across space using available software packages. Nevertheless, for better or worse, researchers have developed confidence in these measures because intrusive changes made purposely in the brains of rats have been correctly picked up by fMRI measures.

The New Unconscious

Since the 1970s, empirical approaches to the study of the unconscious have differed from Freud's notions, with exception of the defense mechanisms. Approximately 98% of our brain processes are unconscious. So 2% of the brain is conscious, but given the vastness of the human brain, this is more than enough. The evidence for the breadth of the unconscious is such that it demands attention. Most of what the brain does is 'procedural,' having to do with routine processes, such as breathing, perceiving 'unities' rather than separate attributes of objects, and learning balance, grammar, and feeling. The brain does these things automatically, which leaves us free for other critical tasks. The other dimension of the unconscious has to do with 'content,' i.e., unconscious fears and cognitions, defense mechanisms, emotions, and memories. When patients with amnesia were pinpricked or shocked by doctors who saw them soon after the onset of amnesia, the patients shied away from the doctors, even though they had no conscious memories of the abuse. In another study, patients with amnesia were placed with three groups of studiers' confederates: The first group was instructed to be pleasant to the patients; then the patients were placed with others who were instructed to be brusque and then with those who were neutral. The patients were shown photos of the three groups, and they easily picked out those they liked and disliked. Consciously, they had no memories of these experiences but unconsciously, they did.

The first undeniable evidence of unconscious emotion came from Zajonc, who showed that mere exposure to a familiar picture would create a positive feeling for it. Here, exposures of the pictures were presented too quickly for subjects to be aware of them.

Evolution of the Human Brain

The data of evolution are always open to doubt because the fossil record can never tell how many other examples existed before a particular finding. It gives only a minute portion of the actual history. Historically, brain size and its relation to intelligence have been given emphasis, but brain size alone does not produce intelligence, and intelligence can take many forms. Coordination with others and imitating others making stone tools were important to survival. Treating the brain, as it is isolated in the skull instead of functioning socially involving other brains, is an error according to Brothers (2001), who labels this 'neuroism.' The origins of human intelligence are, therefore, better sought in the environmental conditions that shape social life. The environmental changes moving early humans from the forest to the savannah put a survival premium on practical intelligence, emotional control, and social cooperation. Remains were found in the Kenyan savanna of the first of our forefathers, little Australopithecines with brain capacities of 450 cc, less than one-third the size of the brain capacities of *H. sapiens*. Their brains were rounder than those of chimpanzees, and their bone structures implies that they walked upright about 4.4 Ma.

Chimpanzee kinship ties are supported by mutual grooming, which produces opiates and increases solidarity. Group size is limited by the time needed for grooming. The larger the group, the more intergroup skills are needed. This puts survival pressure on these same skills, and it is critical for small animals whose size makes them dependent on forming alliances. Some experts suggest that Australopithecine communication was largely emotional, and emotion still organizes the hominid brain. Emotion also lays the basis for developing cognition and emotional control. The social emotions are, of course, central to group life. All these early characteristics formed the basis of our current social brains and impose limits on them.

Given the dangers of the times, it was probably healthy for the Australopithecine brain to react without much cognitive anticipation. These limits meant that they never wandered off to new environmental niches and were therefore mentally shaped by their environment. Nonetheless, they lasted more than 3.5 My.

Homo habilis arrived at least 2 Ma, and many think they were not that different from the numerous Australopithecines who used 'near' tools sufficient to break bones and eat their marrow. The stone choppers of *H. habilis* were useful only for scavenging. Nonetheless, their brains tripled in size during the one million years they lived. During that time, *H. habilis* never increased the efficiency of their tools. Nor did they have the cognitive capacity to imagine traveling to new places. Brain size does not drive innovation; innovation drives brain size.

Homo erectus arrived on the evolutionary scene 1.8–1.5 Ma. Although brainpower doubled to 1100 cc, they had no vocal organs to develop speech. The frontal and parietal lobes increased, flattening their faces. Females grew larger to accommodate the larger heads that had been developed, so the women could accommodate childbirth. Birth was still dangerous, but the large brain size increased brain development as well as infant dependence, which made things more dangerous for children and mothers. Breasts were enlarged and women were constantly receptive sexually. The brain was also lateralized. The right side allowed emotional communication and increasing sociality. The inventory of tools plus their variety increased. This allowed *H. habilis* to migrate to southern France in warm weather and return to northern Africa in the winter. This required the ability to make mental maps. They lasted one million years with their numerous tools and made no further advancements.

The Neanderthal and *Heidelbergensis* competed with *H. erectus*. The Neanderthal was more robust, more thickly boned, and more muscular. Their brains increased to 1400 cc – larger than the brains of *H. sapiens* brain.

H. sapiens developed in Africa 150 000 years ago. Between 200 000 and 40 000 years ago, they began to talk. Charles Li and Jean-Marien Hombert suggest there is a confluence of evidence that this date was as recent as 80 000–60 000 years ago. For Australopithecine, the amount of time spent grooming others determined group size, but language made grooming unnecessary, and group size was determined by food supplies. Domestication of animals allowed for fixed settlements, expansion of group size, and the advent of cities around 10 000–12 000 years ago.

Consciousness about one's self, was indicated 43 000 years ago when the oldest decorative beads were made. They were brought from great distances that gave them value and reflected concern about one's status and identity.

The Social Nature of the Brain

Leslie Brothers (1997) laid the verbal foundation for neurosociology. The term 'social editor' is Brothers' way of presenting the brain's social structuring. A critical structure here is the amygdala.

The amygdala is critical to socially related memories, as is the hippocampus. A lesson learned but forgotten is not really a lesson learned in the larger picture.

In cases of post-traumatic stress, the amygdala may be quick to learn, but it makes the situation hard to forget. The critical importance of the amygdala is that it enables so much. This includes fear, assessing facial expressions, attachment, unconscious learning, early emotional memory, and emotion across the life span. One should not, therefore, be surprised at its complexity, despite its small size. The amygdala exemplifies how the brain is not perfect. Known as a very fast warning system, it operates at speeds of less than 100 ms, allowing us to know whether an object is safe or not before we know what it is. At such speeds, it is often wrong. But when it is right, it can save our lives. It also assesses the emotions of others in terms of whether they are safe or dangerous. The speed of social interaction is so fast that we need such assessments, and the faster the better, according to many, including Brothers (1997: p. 12).

Mirror Neurons

A mirror neuron fires when we passively observe others perform certain actions. Next, it actively simulates the others' actions unconsciously in the observer's motor cortex. In an important sense, we act behaviorally according to what we watch. These neurons are inherently social and are directed toward the actions of others; they also actively combine motor activity and perception. Furthermore, and most important, mirror neurons fire when the action observed can be seen as reflecting intention on the part of the observed actor. Because it is unconscious, this response prepares for the lightening-quick responses necessary for social interaction. Some researchers have questioned whether mirror neurons are actually present in human beings because measures are so indirect and are limited to the amount of oxygen released in certain areas of the brain. Single-neuron measures are destructive of brain tissues surrounding the neurons in humans. The first direct recording of human mirror neurons used 21 patients with pharmacologically intractable epilepsy. Such research is obviously limited to what is possible in those kinds of cases. Even with that limitation, the researchers found that mirror neurons were more widely dispersed within the human brain than previously thought (Franks and Davis, 2012).

Mirror Neurons and Pragmatism

For researchers in the field of mirror neurons, the relationship between our motor intentions and the way we perceive the world is an 'affordance.' An affordance is something that the environment offers to make behavior possible, such as surfaces that provide support, objects to be manipulated, and substances that can be eaten. The Chicago pragmatists made the same point. They saw the epistemological link between the knower and the known as behavior. It is interesting that this is confirmed by current research into mirror neurons.

Researchers Rizzolatti and Sinigaglia (2008) argue that the visual perception of an object implies the immediate and automatic selection of those properties that facilitate our behavioral interaction with it. We perceive the world not so

much as it is in some final sense, but in terms of how it answers to or facilitates our actions.

Furthermore, our senses of and reasoning about the world are limited. The environment becomes constructed and objectified only in relation to our limited motor capacities, senses, and brains. The German term *Umwelt* captures this organism/environment relationship. It refers to the world carved out for our attention by our own capacities, sensitivities, and motor repertoires.

The research into mirror neurons implies the existence and relevance of just this social behaviorist view. The mirror neurons of dancers respond most strongly to observations of familiar dance steps in line with the style of dancing the observers routinely used. More pointedly, human subjects were shown videos of the motor behaviors of various animals communicating, such as monkeys lip-smacking, dogs barking, and humans talking; mirror neurons became engaged only during the observation of humans talking, even though visually, it was obvious that all behaviors were communications involving moving mouths. Because we have no spaces in our motor cortexes for barking and lip smacking, we cannot simulate them.

Mirror Neurons and Speech

For the social behaviorist George Herbert Mead (1938), human thought and speech were clearly intangible universals. Words represent general terms, subsuming all real particulars. But the process is also behavioral. As humans solve problems, they are really talking to themselves, making subliminal movements with those muscles associated with speech, such as the tongue, lips, and larynx. Deaf children privately thinking to themselves likewise make subliminal hand and body gestures that underlie their symbolic thoughts. The congenitally blind, who have never seen gestures, nonetheless make motor movements when they talk. Gestures are not ancillary to talk but are inherent parts of it, just as grammar is. We even gesture when talking on the phone when no one can see us.

According to Jonathan Turner, thinking is also accomplished in a gestalt-based mode. The Broca and Wernicke areas of the brain change speech into the brain's way of thinking. Because talk is behavioral, we simultaneously enact in our motor cortex the same speech movements others are making. Their talk literally becomes our talk, with the provision that it is automatic and unconscious. The theory of 'embodied semantics' holds that concepts are represented in the brain by the same sensory–motor circuitry on which the concept relies. The general concept of grasping would be represented by increased activity in the sensory motor areas devoted to grasping actions. Language is biologically linked to action through mirror neurons in a way that is congruent with the priority given to action by the pragmatists. Pragmatists would insist that language is not separate from motor behavior but, rather, is inherently grounded in actions. For example, kicking as a conceptual generality would be represented in the sensory–motor space given over to the leg and foot. Even metaphors such as "we will kick off the new year with a party" are represented in these foot and leg areas of the motor cortex. According to these researchers, the hypothesis of 'embodied semantics' has been confirmed by studies of patients with traumatized parts of the motor cortex and fMRI studies that take moving images of the activation of brain parts.

Emotion and Rationality in the Human Brain

Another critical part of the social editor is the often overappreciated prefrontal cortex. It is overappreciated because it is treated as if it stands alone to produce our intellectual capacities. Damasio as well as philosophers and even artificial-intelligence workers have convincingly shown that without certain emotions, we are unable to make the simplest choices. Alone, the prefrontal cortex gives us nothing. Patients traumatized in the ventral medial parts of the prefrontal lobes were capable of anger but incapable of feelings of apprehension, discomfort, or hunches, called 'somantic markers,' that lead us away from bad social associations, especially untrustworthy partners. On the other hand, they were not able to have normal emotions. While interviewers wept at their stories of their familial and business downfalls, they, themselves, felt no such remorse, even though many such patients were quite intellectually capable. Damasio and his wife, Hannah, developed a card game to measure this in which high-paying cards were also risky ones, with some demanding severe payments resulting in losing the game. Unlike normal subjects, these patients never learned to avoid high-paying but high-risk cards because they did not have somantic markers to make them feel apprehensive and reject them. A complete discussion of replications and their pros and cons is available in TenHouten.

Imitation

It is not apes or monkeys who do the aping. Imitation is an ability of humans and results in our capacity to learn from others and thus to pass culture on to other generations. Imitation is not literal or superficial because it must be generalized from situations different from the one where the behavior was first learned. We need to know the intentions of the persons we are imitating. We also simulate others' mouth movements in our motor cortex. Thus, Iacoboni (2008) argues that evolution leads from action recognition through imitation to language.

Infant imitation is hard-wired. Among newborns only 32 h old, the imitation of facial movements is common, even though they cannot see their own faces. The scope of imitation is broad. We imitate those we like, and they like us more commonly if we imitate them. Research using confederates shows how readily participants imitate the smallest movements. Participants primed with stereotypes of the elderly walked more slowly than unprimed ones. Imitation is seen as an unconscious social glue, but it is fragile and must be sustained by role taking and other processes.

The 'correspondence problem' and its solution are prerequisites for a full understanding of imitation. What we see is dependent on our spatial perspective, so the mapping of the motor cortex must make 'corrections.' When, as adults, we imitate expressions, how do we know we are correct when we

can't see our own faces? Solving the correspondence problem involves answers to these questions.

Determinacy and Empirical Evidence for Agency

In 1964 Roger Sperry won the Nobel Prize for his thesis that mind, seen as an emergent from neuronal processes in the brain, can in certain instances exert a causal force capable of changing the parts from which it emerged. Jeffery Schwartz and Sharon Begley (2002) applied Sperry's ideas to human patients suffering from obsessive compulsive disorder (OCD). In about 1969 Edward Traub, who worked with macaque monkeys in an NIH laboratory in Silver Springs, MD, established the experimental foundations for Schwartz's work. Traub clashed with animal-rights workers and was charged with animal cruelty because of his treatment of the monkeys, although his practices were not unusual for the time.

Traub tested the hypothesis that monkeys, whose ability to experience sensations in their arms was removed surgically, retained the capacity for purposeful behavior in those limbs but only if they were forced to use them and then were immediately rewarded. The monkeys were fed only minimally to the point of near starvation; their functioning arms were restrained; and electric shock was administered to them if they did not try to use the disabled arm. Finally, the monkeys regained the use of their once paralyzed arms. Autopsies showed that the somatosensory cortex, controlling feeling from the body to the cognitive prefrontal cortex, had been rezoned using neurons from the face.

In 1992, after he was reinstated into his profession, Traub applied his monkey experiments to humans who had suffered from strokes. In what he called 'constraint induced therapy,' he tied 21 patients' good arms in slings and had them do strenuous exercises with their weak arms. These patients had been paralyzed for an average of four and one half years. They now received therapy for 6 h a day for only 10 days. After only a 2-week session, the use of their once paralyzed arms was recovered and remained so after 2 years. For patients with OCD, Schwartz developed a successful four-step program that included relabeling, reattribution, refocusing, and revaluing. Two brain areas became overactive in OCD that were clearly visible in PET scans. Seeing these areas facilitated relabeling. For example, one woman witnessing this exclaimed, "That's not me, that's my OCD!" She was able to deconstruct her overpowering feelings as brain-driven illusions and separate them from her real self.

The theoretical implications of this for social psychology are significant indeed. First we have the notion of mind as a cognitive symbolic process instead of a reified noun. This allows the conception of mind as an emergent from but different from the deterministic brain. This leaves room for a sound concept of agency. Fuchs (2001), for example, sees agency as a residual category resulting from unexplained variance and then attributed to the actor. The patients who were cured, however, are direct empirical examples of will and the cognition reflecting agency. They demonstrated that mind and symbolic processes are causal forces over matter. This finding joins with those of mirror neurons in helping to explain our natures.

Current Selected Findings Relevant to Neurosociology

Jeff Davis on Persistent Inequality

Davis presents a compelling argument regarding the effects of persistent social inequality on the brain. He contends that structural explanations fall short of explaining the microfoundations of social inequality. Davis uses Tilly's model of inequality to identify four major institutions that weave inequality into the fabric of society: exploitation, hoarding of opportunities, emulation, and adaptation. Davis focuses on the last two processes.

The unpredictable nature of an impoverished environment impacts neural functioning as do other stress producers, creating preferences for short-term rewards and fostering little or no planning for the future as well as aggressive behaviors and higher risks for teenage parenthood. Brain supports for the processes involved in avoiding these behaviors are the prefrontal cortex, the anterior cingulate cortex, and the vertebrate social behavior network. The author links neurotransmitters to decision making, and deficits in the latter are linked to poverty. This means that once in such an environment, actors will have a hard time getting out because of their own behaviors.

Unconscious Voice Signals of Status

Thirteen years ago Gregory reported his findings concerning how to separate and thus analyze various dimensions of the spectral frequencies in human voices. He and his colleagues found that frequencies below 0.5 kHz signaled social status accommodation and social convergence. These original experiments were performed on conversation dyads. In 2002, Gregory and Gallagher demonstrated that analysis of low-frequency spectra from speech in presidential debates could be used to predict winners of eight of the past US elections, from 1960 to 2000. These remarkable findings were successfully replicated in 2008 for the debates between Senators Obama and McCain.

Conclusions

Notably, it was neuroscientists working with sociologists who first formulated the case for neurosociology. The two examples emphasized herein were Bogen, writing with TenHouten, and later Brothers, advised by Perinbanayagam, a symbolic interactionist. It is to be hoped that such interdisciplinary efforts will continue in brain studies.

Two tasks are still left undone for the final maturity of neurosociology. Sociology must be able to inform neuroscience more than it has in the past, and doctorate programs in neurosociology must be developed.

Abstract

The personality dimension of neuroticism, as defined by the trait perspective, refers to relatively enduring tendencies to think and react in anxious and maladaptive ways, and feel more negative emotions. Research has suggested that this personality dimension is universal, having been replicated across cultures and having a strong biological basis. Neuroticism is a robust and strong correlate of various constructs (e.g., emotional disorders, cognitive processes, emotion regulation, and coping) and is also an important predictor of diverse life outcomes (e.g., well-being, mental and physical health, social relationships). Although it demonstrates rank-order stability, extensive evidence indicates that there is mean-level decrease in neuroticism over the life span.

Definition of Neuroticism: A Trait Perspective

Traits refer to generalized and personalized tendencies – that is, consistent and stable modes of an individual's adjustment to his or her environment. In contrast to the nomothetic approach, which studies trait units that apply to all people, the idiographic approach emphasizes that every individual is unique and different, and general principles cannot be broadly applied to all people to understand and predict their behaviors. Although the concept of traits originated from Allport, the main emphasis of the modern-day trait approach has now diverged. The trait approach is now geared toward a descriptive and comparison orientation rather than being grounded in explanatory purposes. Though lacking in accuracy, as the trait approach does not provide a comprehensive theory of personality, theories based on this approach provide diverse perspectives, ranging from viewing traits as descriptive concepts to viewing them as biologically based causal concepts. The merits of this approach are that it is a convenient method for assessing personality characteristics and comparing people, and it provides a heuristic way of making predictions and judgments.

The most popular and commonly used trait theories are based on Costa and McCrae's five-factor model (FFM) and the Big Five (Costa and McCrae, 1992; John and Srivastava, 1999). Factor-analytic studies originating from Goldberg's lexical tradition and factor analyses of personality questionnaires consistently converged to yield five factors (Costa and McCrae, 1992; Goldberg, 1990), and the lexical and questionnaire traditions were merged to produce a five-factor structure. The Big Five dimensions are extraversion, agreeableness, conscientiousness, neuroticism, and openness to experience. Extraversion assesses the quantity and intensity of interpersonal interaction, and one's activity level, need for stimulation, and capacity for joy. Agreeableness refers to a prosocial and communal orientation toward others and assesses the quality of one's interpersonal orientation along a continuum from compassion to antagonism. Conscientiousness describes the extent that an individual possesses socially prescribed impulse control such as delaying gratification, following norms and rules, organization, and persistence. Openness to experience describes the breadth, depth, originality, and complexity of an individual's mental and experiential life. It assesses an individual's proactive seeking and appreciation of experience and exploration of the unfamiliar. Finally, neuroticism assesses an individual's adjustment versus emotional instability. This personality dimension identifies individuals prone to psychological distress, unrealistic ideas, excessive cravings or urges, and maladaptive coping responses. Individuals who are low on neuroticism are calm, secure, and emotionally stable, whereas those high on neuroticism tend to be emotionally unstable and show characteristics of being anxious, depressed, moody, and irritable. Based on the NEO Personality Inventory – Revised (NEO-PI-R), the FFM further differentiates the broad domain of neuroticism into the facets of anxiety, angry hostility, depression, self-consciousness, vulnerability, and impulsiveness (Costa and McCrae, 1992).

The five-factor theory (FFT) posits that these five basic dimensions correspond to basic psychological tendencies in every individual and are biologically based. These personality dimensions interact reciprocally with external influences (e.g., cultural norms, life events) to influence characteristic adaptations (e.g., an individual's thoughts, feelings, and behaviors) (McCrae and Costa, 2008). The FFT assumes that these basic tendencies are uniform across cultures and are universal; this universality might be attributed to the species-wide biological bases of traits or might represent a psychological consequence of the shared human experiences of living in societies where similar life tasks might be promoted by most modern cultures (McCrae and Costa, 1997).

Universality of Neuroticism

Across the myriad of personality theories, various researchers have conceptualized neuroticism distinctively, assigning different labels to it (e.g., neuroticism, negative emotionality, negative affectivity, emotional instability). Yet, despite the disparate labels and definitions, the common underlying characteristics across the various personality models signal that they are referring to a fundamentally similar personality construct. For instance, although Eysenck's three-factor personality theory comprises only three basic dimensions – psychoticism, extraversion–introversion, and neuroticism – neuroticism as conceptualized in his theory is similar to that

in the FFM. It also subsumes lower-level traits such as worrying, anxious, depressed, moody, and emotional instability. Eysenck's three-factor theory emphasizes the biological determinants for the three superfactors, and he hypothesized that the biological basis for neuroticism stems from the autonomic nervous system; those higher in neuroticism have lower threshold activation in the autonomic nervous system (Eysenck, 1990). Equivalence can also be drawn between Tellegen's three- (or four-) factor model and the Big Five model. Assessed by the Multidimensional Personality Questionnaire (MPQ; Tellegen, 1985), Tellegen's model comprises positive emotionality, negative emotionality, and constraint (and absorption). Commonalities exist between the negative emotionality factor and neuroticism – individuals high in negative emotionality have a low threshold for the experience of negative emotions and tend to be involved in antagonistic relationships. Factor analyses indicated that the Big Five constructs can be subsumed under Tellegen's four dimensions because negative emotionality encompasses neuroticism and (the inverse of) agreeableness. Therefore, despite its varying labels, the conceptualization and inclusion of the neuroticism construct across different personality theories suggests that it is a universal personality dimension.

The replication of the neuroticism construct across cultures reinforces the notion that it is a universal personality dimension (McCrae and Costa, 2008). The FFM personality structure (including neuroticism) has been consistently replicated across cultures. For example, the same FFM based on American adults was replicated with German, Israeli, Korean, and Chinese adults (McCrae and Costa, 1997). Lexical studies also found cross-language agreement on the five factors – studies of German traits (using German adjectives) replicated the English-language five factors and clearly recovered the FFM, and Chinese trait terms also yielded five dimensions that overlap considerably with the Big Five dimensions. In sum, various cross-cultural studies, including a large-scale observer rating study across 50 different cultures, provide clear evidence for the universality of the FFM across different instruments and measurement methods (McCrae and Costa, 1997, 2008; McCrae and Terracciano, 2005).

Another line of evidence that supports the universality of neuroticism is its biological basis. Twin studies comparing monozygotic (MZ) and dizygotic (DZ) twins provide some evidence that neuroticism has a biological basis and is partly heritable. MZ twins correlated much higher (0.46) than DZ twins (0.2) on neuroticism. However, results from adoption studies undermine these findings that highlight the importance of genetic influence on neuroticism. Correlations between biological parents and their adopted-away offspring were almost zero, suggesting that the high correlations between MZ twins might have been partly caused by their more similar environments (Plomin and Caspi, 1999). To circumvent this problem and control for environmental effects, researchers compared reared-apart and reared-together MZ twins. Though various studies diverge on their estimates of the heritability of neuroticism (some found lower correlations for reared-apart MZ twins (0.25) than reared-together MZ twins (0.41), whereas others found similar correlations for reared-apart and reared-together MZ twins), the overall evidence indicates that neuroticism is partly biologically determined and heritable to some extent (Pedersen et al., 1988; Plomin and Caspi, 1999). In recapitulation, the replication of neuroticism across cultures and personality models and its biological basis substantiate the conclusion that it is a universal personality trait.

Links between Neuroticism and Other Constructs

Emotional Disorders

Before the *Diagnostic and Statistical Manual of Mental disorders* (*DSM-III*), early DSM-based categories of mood disorders included the clinical label of neurosis, which comprised individuals showing anxiety and depressive disorders. The personality trait neuroticism, however, is independent of the construct of neurosis. Subsequent editions of the *DSM* stopped employing the diagnosis of neurosis and instead classified patients into specific anxiety or mood disorders. Yet, the growing evidence highlighting the strong associations between neuroticism and various mental disorders suggests that neuroticism may represent a broad, underlying syndrome common across the disorders (Barlow et al., 2013).

In their review, Barlow et al. (2013) summarized theoretical and empirical evidence underscoring the role of neuroticism in the development and course of emotional disorders. First, there are high rates of comorbidity among anxiety and mood disorders. Second, treatments for a specific disorder often improve comorbid anxiety/mood disorders that are not targeted, demonstrating broad treatment responsiveness that may possibly be due to common features among different disorders. Finally, neuroscience evidence suggests that emotional disorders may share a common biological syndrome related to hyperexcitability of limbic structures (e.g., amygdala overactivation, limited cortical inhibition of amygdala responses). Likewise, individuals high in neuroticism exhibit similar amygdala overactivation. These three areas support the conception that there are commonalities among anxiety and mood disorders, which may arise from a broader, temperamental syndrome (i.e., neuroticism). These commonalities can be traced to the underlying structure of emotional disorders that are defined by the two core dimensions of neuroticism and extraversion (Barlow, 2002). The higher-order dimension of neuroticism explained most of the covariance among various anxiety and mood disorders (e.g., depression, social anxiety disorder, panic disorder) (Barlow et al., 2013).

The triple-vulnerability theory formulated by Barlow and colleagues serves as a framework to explain the origins of neuroticism and emotional disorders. The two generalized vulnerabilities in the theory – (1) a biological vulnerability that is heritable and (2) a psychological vulnerability that stems from adverse early experiences and predisposes one to a sense of unpredictability and uncontrollability – are hypothesized to be risk factors for the development and expression of neuroticism. When subjected to stressful environmental contexts, people with these two vulnerabilities develop a generalized, anxious syndrome. The last element of the theory – a specific psychological vulnerability (which is mainly learned) – accounts for why a particular form of emotional disorder is manifested. Given that trait neuroticism underlies the roots of anxiety and mood

disorders, Barlow and colleagues proposed that psychological interventions and treatments directed at addressing this temperamental vulnerability may yield greater success than traditional treatments targeting the symptoms of specific disorders.

Emotion

As reflected by its conceptualization and definition, neuroticism should be closely related to emotions. Indeed, numerous correlational, experimental, and longitudinal studies have converged on the conclusion that neuroticism is positively linked to negative emotions (e.g., Diener and Lucas, 1999; Tellegen, 1985; Watson and Clark, 1984). This robust relation has also been found across various cultures, where neuroticism predicted unpleasant affect over a period of 10 years. The temperament perspective posits that the biological basis of neuroticism leads to predilections to experience negative affect. Emerging research has begun to pinpoint some of these neurobiological bases; for example, high levels of neuroticism are linked to excessive sensitivity of the amygdala and low serotonin levels. This temperament perspective is also supported by heritability studies, demonstrating that genetics account for about 31% of the variance in neuroticism (Pedersen et al., 1988).

Temperamental differences in emotions can result from differences in reactivity or baseline affect (or both). According to the reactivity model, individuals high in neuroticism react more strongly to negative stimuli – this differential reactivity to emotional stimuli accounts for neuroticism differences in emotional experiences (Gross et al., 1998). In support of the reactivity model, experimental studies found that neuroticism was associated with higher negative emotions in unpleasant situations. Recent functional imaging studies also confirm that neuroticism is associated with brain reactivity to negative emotional stimuli (Canli et al., 2001). Ecologically valid studies examining naturalistic affective responses have also replicated the experimental findings. Diary studies, for example, documented that participants higher in neuroticism were more reactive to stress and showed a stronger association between daily stress and daily negative affect (e.g., Mroczek and Almeida, 2004). Another model, the affect-level model, posits that differences in neuroticism lead to differences in tonic levels of negative affect; hence, those high in neuroticism feel more negative regardless of the circumstances or stimuli (Diener and Lucas, 1999; Gross et al., 1998). In support of both models, studies by Gross et al. (1998) found that neuroticism correlated positively with baseline negative affect and with increases in negative emotions in response to unpleasant stimuli.

Cognitive Processing

According to the cognitive perspective, individual differences in cognitive processes or cognitive processing of emotional information can also account for neuroticism differences in emotional experiences (Rusting, 1998). Cognitive processes refer to ways of encoding and categorizing information, expectancies about outcomes and self-efficacy, self-regulatory processes, or coping styles. Personality theories like the FFT and the cognitive-affective processing system (CAPS) that incorporate additional elements (e.g., dynamic processes) and do not focus solely on traits may shed some light on how neuroticism differences in cognitive processing arise. The FFT postulates that the five factors (i.e., basic tendencies) interact with external influences through dynamic processes (such as cognitive styles) to shape characteristic adaptations. In turn, some dynamic processes can be differentially affected by personality traits (McCrae and Costa, 2008). CAPS theory conceives personality as a system characterized by interrelated cognitive and affective units that interact dynamically. Individual differences in behavioral and affective responses to the external environment are due to individual differences not only in the accessibility of particular cognitive-affective units but also in the distinctive organization and chronic activation levels of these units. Dynamic reciprocal transactions occur not only between this personality system and the external environment but also within the system, among the social-cognitive and affective variables (Mischel and Shoda, 1995).

Extant evidence does support the view of a more comprehensive system, where personality traits interact reciprocally with other processes (e.g., cognitive styles, affect). Other than affect (as discussed in the earlier section), neuroticism also influences cognitive processing. Studies have shown that individuals higher in neuroticism demonstrate a cognitive processing bias toward negative stimuli. For instance, high-neuroticism individuals recalled more negative words, exhibited a negative attentional bias, and responded faster to targets located with negative words. Not only do they process and recall negative stimuli faster and better on various cognitive tasks, they also interpret ambiguous stimuli negatively (Rusting and Larsen, 1998). Individuals high in neuroticism also tended to appraise the environment negatively (Watson and Clark, 1984). The superior processing of trait-congruent emotional information may be one possible explanation for why high-neuroticism individuals experience stronger negative emotions.

Emotion Regulation and Coping

The close associations between neuroticism and emotional experience also extend to emotion regulation. Neuroticism predicts efforts to control emotions, and correlational findings have revealed neuroticism differences in positive and negative emotion regulation (e.g., Gross, 1999). Tendencies to diminish or eliminate one's negative emotions or turn them in a more positive direction correlated inversely with neuroticism. This means that those higher in neuroticism are less likely to improve their negative mood or cope with negative outcomes and their emotional impact. They are also less likely to savor positive affect. Usage of the emotion regulation strategy, reappraisal, which leads to lower negative emotions and more positive emotions, is also correlated negatively with neuroticism (Gross and John, 2003). The link with emotion regulation extends beyond a concurrent association, as neuroticism also predicts future emotion regulation. Prior neuroticism predicted lower use of strategies to repair negative emotions at a later age (Kokkonen and Pulkkinen, 2001). Hence, the evidence

consistently documents that neuroticism is associated with use of maladaptive emotion regulation strategies.

Coping processes, which are considered as a type of cognitive process that people undergo when dealing with stressful or difficult events, have also been increasingly linked to neuroticism. Neuroticism relates to negative dispositional coping styles and cognitive appraisals and is consistently found to be associated with the use of ineffective coping mechanisms. High-neuroticism individuals also tended to use less adaptive coping strategies to cope with the daily stressors than low-neuroticism individuals. The links between neuroticism and coping were further confirmed in a meta-analysis, which found that neuroticism predicted specific problematic coping strategies like withdrawal, wishful thinking, and negative emotion-focused coping (Connor-Smith and Flachsbart, 2007).

Neuroticism not only exerts direct effects on constructs, such as emotion, emotion regulation, and cognitive processes, but also plays an important moderating role. For instance, not only does neuroticism affect people's emotional reactivity to stressors and their choice of coping strategies, it also moderates the efficacy of those coping strategies (Bolger and Zuckerman, 1995). There is also evidence that neuroticism moderates the effectiveness of cognitive strategies on emotion regulation. Reappraising an unpleasant real-life event or a hypothetical situation decreased negative emotions among low-neuroticism, but not among high-neuroticism, individuals (Ng and Diener, 2009). Conversely, negatively reappraising a positive event to dampen it decreased positive emotions among high-neuroticism, but not low-neuroticism, individuals. Hence, cognitive strategies have differential effects on positive and negative emotions for people varying in neuroticism. High-neuroticism individuals are less proficient at negative mood repair, but yet are more susceptible to the detrimental effects of maladaptive strategies.

Life Outcomes

In summary, the links between neuroticism and the various constructs highlight that neuroticism would predict outcomes in important life domains. A review of the extensive literature on the relationship between personality and subjective well-being confirmed that neuroticism is linked to lower well-being (Steel et al., 2008). People higher in neuroticism are lower in happiness and life satisfaction and experience greater negative affect. Neuroticism is also inversely related to the overall quality of life. Furthermore, neuroticism is closely associated with and predictive of mental and physical health. Extensive evidence indicates that it strongly correlates with mood, anxiety, somatoform, eating disorders, and schizophrenia, and correlates moderately with personality disorders. It is also associated with physical health problems such as cardiovascular disease and even predicts longevity in the general population (Lahey, 2009). However, a recent longitudinal study suggests that high neuroticism, when accompanied by high conscientiousness, can still be associated with some health benefits. Specifically, people who were high in both neuroticism and conscientiousness had lower levels of interleukin-6; that is, they had lower health risk for chronic diseases such as heart disease (Turiano et al., 2013).

In the work domain, negative emotionality (or neuroticism) predicted future work outcomes: Those higher in negative emotionality at age of 18 years subsequently had lower levels of occupational attainment, less job satisfaction, and less financial security at age of 26 years (Roberts et al., 2003). In the social domain, neuroticism is a consistent personality predictor of relationship outcomes (e.g., relationship dissatisfaction, conflict, abuse) and relationship quality (Caspi et al., 2005). It is also inversely related to marital satisfaction (Lahey, 2009). Therefore, work from different areas converges to underscore the pivotal role of neuroticism in life and how it serves as a robust and important correlate and predictor of key outcomes. Overall, the evidence underlines that higher neuroticism is related to more adverse outcomes – being less happy, less healthy, and less successful, although it may be associated with some health benefits when combined with other personality traits (e.g., conscientiousness).

Change in Neuroticism across the Life Span

Longitudinal studies on personality have shown that personality traits (such as neuroticism) are not fixed and can change over time. Despite its strong genetic basis and the belief that genes do not change, neuroticism is not entirely determined by genes and can also be influenced by environmental factors and the interactions between genes and environment. For instance, if one's environment does not fit with one's existing genetic predisposition, one can try to change the environment (manipulative process) or try to change one's personality traits to achieve a more congruent person–environment fit. Hence, as environments change and interact with genes via bidirectional and dynamic processes, these experiences can affect neuroticism change. Although people change as they age, there is still overall consistency in personality. A meta-analysis of longitudinal studies demonstrated high rank-order consistency (i.e., the relative ordering of individuals within a group over time) for the Big Five personality traits, as all five traits were fairly stable (with consistency estimates ranging from 0.5 to 0.55), with neuroticism showing a stability coefficient estimate of 0.50 (Roberts and DelVecchio, 2000).

Indeed, personality continuity is exhibited from childhood to adulthood. Childhood temperamental qualities are closely linked to adult personality traits. Findings indicated that children who exhibited the undercontrolled temperament type at age of 3 years showed high levels of negative emotionality (or neuroticism) at ages of 18 and 26 years (Caspi et al., 2003). Longitudinal and cross-sectional studies of personality trait change confirm that personality traits continue to change in adulthood, and even into old age (Roberts and Mroczek, 2008). Cross-sectional findings that middle-aged individuals are lower in neuroticism than young adults are corroborated by longitudinal studies that showed that there is increased emotional stability with age (Roberts et al., 2006). This mean-level change in neuroticism (i.e., the increases/decreases over time in a sample/population of individuals) occurs throughout the life span, starting from adolescence,

with larger decreases in young adulthood (age of 20–40 years), though people continue to decrease in neuroticism in middle and old age (Roberts et al., 2006).

This decline in neuroticism has been replicated across cultures, suggesting that its developmental trend is universal. Indeed, there is strong evidence of universal personality maturation, where neuroticism showed age-related decreases across 62 nations (Bleidorn et al., 2013). Consistent with the FFT perspective that personality traits are biologically determined, there should be no cultural differences in personality developmental trends. Yet, there is also evidence of significant cultural differences in age effects on personality traits across the 62 cultures; specifically, cultures with earlier job-role transitions showed more pronounced age-related decreases in neuroticism. Hence, these findings also support the social investment theory, which proposes that cultural norms regarding the timing of life transitions (e.g., family-role and job-role transitions) influence personality maturation (Bleidorn et al., 2013). That is, investment in social roles contributes to personality development.

Why do personality traits change over time? Although personality is partly determined by genes, personality change can occur via mechanisms such as life and work experiences, changes in cultures and social environments, and changes in expectancies and goals. Work and life experiences are a major factor for why people change as they age. Roberts et al. (2003) found that work experiences were related to changes in personality traits. For example, occupational attainment, work satisfaction, and financial security were related to decreases in negative emotionality (as assessed by the MPQ). Similarly, increases in work satisfaction and relationship satisfaction were associated with decreases in neuroticism (Scollon and Diener, 2006). In recapitulation, personality traits do change due to life experiences and through interactions with one's environment and culture.

Conclusion

It is evident that neuroticism is not merely a descriptive personality trait for comparing people. Neuroticism is also a strong predictor of emotion, mental and physical health, work outcomes, and social relationships. Its close links to adverse outcomes in important life domains highlight that it is germane to understand the mechanisms underlying these links. Development of models that would explain the causal relations between neuroticism and these life outcomes, as well as examine potential interventions or treatments, would be important. Such interventions could help to improve or even prevent the undesirable outcomes associated with high levels of neuroticism. For example, in the area of mental disorders, treatments that target temperamental vulnerabilities could be developed, as they would address commonalities underlying various disorders and would be more effective than treatments targeting symptoms. Additionally, future treatment approaches could examine ways of reducing high levels of neuroticism. This is pertinent, given that there is potential for change in neuroticism although it exhibits fairly large rank-order stability, as substantial evidence has noted mean-level decreases in neuroticism across the life span.

Abstract

Neurotransmitters act as signaling molecules between neurons and other neuronal or nonneuronal cells. They relay information across chemical synapses, whereby their effect, *in concreto*, depends upon the respective receptor they bind to. All known neurotransmitters have several different types of receptors they are capable of binding and, as such, are functionally highly versatile. They, additionally, share many commonalities with other signaling agents. Important neurotransmitters in mammals are acetylcholine, monoamines (like serotonin, dopamine, adrenalin, and noradrenalin), glutamate, and gamma-amino butyric acid. Changes in neurotransmission constitute, i.e., the first step in synaptic plasticity, the neural foundation of learning and memory.

Neurotransmitters are a group of signaling molecules that are synthesized and released by neurons. Prior to the discovery of enlargements in the gaps between axon terminals and other cells (the synaptic cleft) by Santiago Ramón y Cajal, signal transduction in the nervous systems was believed to be primarily electrical via so-called gap junctions. The first neurotransmitter was discovered in 1921 by Otto Loewi, who named it *Vagusstoff* due to its properties to mimic the inhibitory effects of the vagus nerve on the heart of the frog. *Vagusstoff* has since internationally come to be known as acetylcholine.

Definition

Due to the works of Loewi and other ensuing research, a number of criteria were laid down in the 1960s to classify neurotransmitters and distinguish them from other signaling molecules; e.g., hormones, neuromodulators, or neuropeptides. These criteria were briefly as follows:

1. Precursors and/or synthesizing enzymes must be present in the presynaptic neuron.
2. The molecule must be present in the presynaptic neuron and be released upon specific stimulation.
3. The available quantity must be sufficient to exert influences on postsynaptic cells.
4. Postsynaptic cells must have receptors capable of binding the molecule.
5. A deactivating biochemical mechanism must be present.
6. Antagonists or blockers must exist to inhibit the molecule's effect on postsynaptic cells.

Due to ongoing research, the development of new methods to identify potential neurotransmitters and the discovery of novel neurotransmitters, the aforementioned criteria have since been found to be mainly underinclusive and have, therefore, lost much of their importance. The most often cited example hereof is the gaseous molecule nitric oxide (NO), which – alongside a variety of other functions – also acts as a neurotransmitter. Due to its ability to diffuse through cell membranes it is, however, not necessarily bound to a single synapse, but instead may also retrogradely influence a number of cells adjacent to the releasing neuron (e.g., astrocytes). It is also not necessarily enzymatically degraded due to its radical nature and brief half-life, or it may react with intracellular superoxide anions to form peroxynitrite, although a number of NO-degrading mechanisms exist within the cellular redox pathways. Finally, due to its primary physiological mechanism of action – i.e., the activation of soluble NO-sensitive guanylyl cyclase – it does not have a receptor in the classic sense.

This issue is further complicated by the fact that a number of molecules – e.g., the monoamines serotonin (5-HT), dopamine (DA), noradrenalin (NA), and adrenalin (A) – act both as neurotransmitters as well as hormones in discrete bodily systems of communication.

It could, therefore, be concluded that the aspect of defining neurotransmitters has taken a back seat to the investigation of the actions of individual signaling molecules.

Classes of Neurotransmitters

Neurotransmitters belong to several distinct (bio)chemical groups. They are generally small nonpeptide molecules that are not encoded by genes but rather (mostly enzymatically) synthesized from precursors taken up with nutrition.

Monoamine transmitters are derivatives of essential amino acids, whereby serotonin (5-hydroxy tryptamine, 5-HT) is synthesized from tryptophane through the enzymes tryptophane hydroxylase and aromatic L-amino-acid decarboxylase. The catecholamines dopamine (DA), noradrenalin (NA), and adrenalin (A) are synthesized from each other starting from the amino acid tyrosine, which is converted to DOPA (3,4-dihydroxy phenylalanine) through tyrosine hydroxylase. DOPA is then metabolized to dopamine through aromatic L-amino-acid decarboxylase (aka DOPA-decarboxylase) and is then taken up into presynaptic vesicles via the vesicular monoamine transporter 2 (VMAT2). In (nor)adrenergic cells or chromaffine cells of the adrenal medulla, these vesicles possess membrane-bound dopamine-β-hydroxylase (DBH) producing noradrenalin. In adrenergic and chromaffine cells, noradrenalin is released back into the cytoplasm via the VMAT1 and here converted into adrenalin through phenylethenolamine-N-methyltransferase.

All monoamines are degraded through monoamine oxidases (MAOs), which exist as two isozymes, MAO-A and MAO-B. Serotonin may additionally be metabolized to melatonin in the pineal gland. Unlike 5-HT, catecholamines are additionally degraded through catechol-*O*-methyltransferase. An example of DA synthesis and degradation is given in Figure 1.

Acetylcholine (ACh) is metabolized from choline and actyl-CoA through choline-acetyltransferase and degraded through acetylcholine esterase forming choline and acetate, whereby the latter may be combined with coenzyme A to form new acetyl-CoA.

Glutamate (Glut) and gamma-aminobutyric acid (GABA) are both derivatives of the amino acid glutamic acid. Glut is the dissociation product of glutamic acid and can either be degraded through glutamate dehydrogenase to α-ketoglutarate or decarboxylased through glutamate/glutamic acid decarboxylase to form GABA, which in turn is degraded through GABA transaminase and succinate semialdehyde dehydrogenase to form succinate. Glut can additionally be synthesized from the amino acid glutamine through glutaminase.

An important fact to mention is that the commonly found classification of inhibitory versus excitatory neurotransmitters is strictly speaking a misnomer, since the action of any given neurotransmitter is not an inherent property of the molecule but rather determined through the individual receptor it binds to (see Section Neurotransmitter Receptors). Even though, e.g., glutamate usually has excitatory and GABA inhibitory effects on other cells, receptors with vice versa effects exist for both transmitters.

Neurotransmitter Systems

While glutamate and GABA as well as other related transmitters like aspartate are produced by a multitude of cells within the entire central nervous system (CNS), phylogenetically older transmitters like acetylcholine and the monoamines are usually only produced by distinct cell populations. These cells are mainly located within the brain stem (with the important exception of the cholinergic motoneurons of the spinal cord and the telencephalic Ncl. basalis of Meynert, which produces acetylcholine, but is only found in this form in *Homo sapiens*) and possess long axons transporting the transmitters to various regions of the CNS. These axon tracts are referred to as neurotransmitter systems, whereby some have additional individual names.

Apart from the aforementioned cholinergic neurons of the spinal cord and the Ncl. basalis of Meynert, acetylcholine is mainly produced in a diffuse network of nuclei within the

Figure 1 Enzymatic dopamine metabolism. Reproduced from Grant, P., 2011. Dopamine Neurotoxicity, Oxidative Stress and Schizophrenia – *In Vitro* and *In Vivo* Studies of Peroxisomal Reactions to Increased Dopamine. Giessen, University, Diss. URN: urn:nbn:de:hebis:26-opus-84954.

reticular formation of the brain stem. These neurons are believed to regulate arousal states both during sleep (induction of REM-phases) and waking hours, probably through projections to the Ncl. basalis of Meynert, and are therefore referred to as the ascending reticular activation system (ARAS). Many older sources link the ARAS to parts of the dorsal thalamus, called the unspecific thalamic nuclei or the truncothalamus, reporting a diffusely arousing function of these nuclei on the cerebral cortex. A vast number of publications of the early twenty-first century have, however, conclusively disproven this notion as well as the existence of the proposed unspecific thalamic nuclei in general.

The 5-HT-system originates from neurons of the midline group of the reticular formation, the raphe nuclei. The axons of the raphe nuclei project in descending (to the spinal cord), transverse (to the cerebellar cortex), and ascending fashion (to other parts of the brain stem, diencephalon, basal ganglia, and cerebral cortex). 5-HT mainly has a modulatory function on other discrete systems; e.g., ascending and descending pain-inhibition systems or modulation of cerebellar function through inhibition of Lugaro's neurons in the cerebellar cortex. According to Richard Depue, the cerebral 5-HT-projections modulate the stimulus-threshold of approach–avoidance reactions.

Noradrenalin and – to a lesser extent – adrenalin are mainly produced in the locus caeruleus located in the tegmentum of the pontomesensephalic border. The locus caeruleus projects, similar to the raphe nuclei, to a variety of regions within the brain stem, diencephalon, and forebrain. These projections have important functions regarding the regulation of central immunomodulatory processes, activation phases during sleep (induction of slow-wave sleep) and, according to the reinforcement sensitivity theory by Jeffery Gray, responses to potentially threatening external stimuli.

Dopaminergic projections, unlike those of other monoamines, form three discrete systems, whereof one originates in the hypothalamus and projects to the anterior lobe of the pituitary. Within this tubero-infundibular system, however, dopamine does not act as a neurotransmitter but as a hormone inhibiting the secretion of prolactin, and is therefore referred to as prolactin-inhibiting hormone. The two classical dopaminergic neurotransmitter systems both originate from the mesencephalon. The nigrostriatal system projects from the compact part of the substantia nigra (SNC) as well as the paranigral and retrorubral nuclei and projects via the median forebrain bundle to the dorsal striatum, where it modulates striatal gating. Due to the extremely high neurotoxicity potential of dopamine, the SNC cells are prone to neuronal death resulting in severe motor symptoms. The resulting clinical picture is called Parkinson's disease.

The second meso-telencephalic DA-system connects the ventral tegmental area with almost all components of the limbic system (e.g., the lateral hypothalamus, accumbens nucleus, hippocampus, amygdala, and the prefrontal and cingulate cortices) and is therefore referred to as the mesolimbic system. Due to the works of Olds and Milner (1954) and Crow (1972) on intracranial self-stimulation in rats, the mesolimbic system was for a long time believed to represent a reward and approach system. More recent findings have, however, shown that it is also involved in the processing of aversive stimuli and avoidance behavior (in the sense of negative reinforcement), wherefore it is today better referred to as conveying incentive salience of (mainly conditioned) stimuli. Dysregulation of this system is considered as one of the main factors in the ethiopathogenesis of psychosis (e.g., in schizophrenia).

Mechanisms of Neurotransmitter Action

Neurotransmitters usually act within chemical synapses by transducing information across the synaptic cleft. They are mostly taken up into vesicles within the synthesizing neuron by specific vesicular transporters and stored for action potential-dependent release. This uptake applies to both newly synthesized transmitters as well as to those that have been reuptaken from the synaptic cleft by so-called neurotransmitter transporters. This storage has been shown to be of great clinical relevance, since some transmitters – e.g., dopamine – have been shown to have neurotoxic effects, which are attenuated by higher pH values within the synaptic vesicles. The deleterious side effects of the drug methamphetamine (aka Chrystal Meth), e.g., are caused by the drug's inversion of the flow direction of both the vesicular transporter as well as the dopamine transporter, whereby methamphetamine acts as a potent dopamine releaser and rapidly induces dopamine neurotoxicity.

Upon an action potential reaching the presynaptic terminal, voltage-gated Ca^{2+} channels open, thereby allowing for the fusion of the synaptic vesicle with the presynaptic membrane and the exocytosis of a large amount of neurotransmitters into the synaptic cleft. The amount of transmitters stored within one vesicle is called a neurotransmitter quantum. Due to the continuous presence of Ca^{2+} ions in healthy cells, single quanta are released all the time, but do not suffice to exert significant influences on other cells. For this effect, the release of several quanta is necessary.

The released transmitters diffuse across the synaptic cleft and bind to receptors present on the membrane of postsynaptic cells. In most chemical synapses, neurotransmitters additionally bind to receptors within the membrane of the presynaptic neuron (autoreceptors), thereby contributing to the inhibition of synaptic transmission via a negative feedback mechanism. In other cases – e.g., within a majority of the synapses using the transmitter glutamate (Glut) – the negative feedback is achieved through more complicated mechanisms. Here, a specific postsynaptic receptor (the NMDA-receptor, named after its primary agonist *N*-methyl-D-aspartate) allows for the influx of Ca^{2+} ions into the postsynaptic cell, which in turn activates, i.a., the enzyme neuronal nitric oxide synthase (nNOS). As mentioned before, NO is then able to diffuse to neighboring astrocytes, where it activates enzymes that degrade important cofactors necessary for NMDA-receptor activation.

Apart from negative feedback and reuptake as well as similar uptake of neurotransmitters into astrocytes via neurotransmitter transporters, neurotransmitter action is also terminated through transmitter-degrading enzymes.

Finally, most synapses are complex, meaning that presynaptic neurons (regarding an individual synapse) are simultaneously the postsynaptic neuron of a second individual synapse and therefore possess receptors for the neurotransmitters used in the second synapse. From the point of view of the first synapse, these receptors are therefore called heteroceptors since they bind neurotransmitters other than the one

Figure 2 Dopaminergic synapse. From Grant, P., 2011. Dopamine Neurotoxicity, Oxidative Stress and Schizophrenia – *In Vitro* and *In Vivo* Studies of Peroxisomal Reactions to Increased Dopamine. Giessen, University, Diss. URN: urn:nbn:de:hebis:26-opus-84954.

produced by the presynaptic neuron. These heteroceptors may either facilitate or inhibit neurotransmission within the synapse, depending on their relative type (see Section Neurotransmitter Receptors).

An exemplary dopaminergic synapse is shown in Figure 2.

Additionally, a number of neurons – e.g., of peripheral axons belonging to the vegetative nervous system or those projecting from the hypothalamus to the posterior lobe of the pituitary – exhibit axonal tumescences, at which transmitters are released into the surrounding parenchyma. These synapses do not 'belong to' individual postsynaptic cells or correspond to the structure of classical chemical synapses and are therefore called *synapses en passant*.

A final important subtype of chemical synapses is the neuromuscular junction, a connection between axons of motoneurons of the spinal cord and skeletal muscle fibers. These synapses exclusively use the neurotransmitter acetylcholine and are, unlike other synapses, completely surrounded by Schwann cells (neurolemmocytes).

Neurotransmitter Receptors

Neurotransmitter receptors are transmembrane proteins consisting of various subunits. In general, they have two distinct features, namely the capacity of binding specific molecules (ligands) and the ligand-gated stabilization with a specific conformational state, which influences either the function or the structure of the receptor proteins. It has to be mentioned, however, that some ligands actually do not influence the receptor conformation, but only block the receptor's binding site for other ligands. These ligands are called competitive antagonists or blockers, while those that inhibit the actions of primary ligands by changing receptor conformation are noncompetitive antagonists/blockers. Ligands mimicking the effects of the primary ligand are referred to as receptor agonists.

Neurotransmitter receptors may be classified into four groups depending on their effect on the postsynaptic cell, which may be excitatory or inhibitory, and their biochemical mechanism of action, which may be ionotropic (i.e., the receptor is a ligand-gated ion channel, which will open upon binding of the primary ligand or an agonist) or metabotropic (i.e., the receptor influences an intracellular signaling cascade upon binding of the primary ligand or an agonist). The resulting four neurotransmitter receptor groups are ionotropic excitatory, ionotropic inhibitory, metabotropic excitatory, and metabotropic inhibitory.

Ionotropic receptors are made up of up to five subunits, which form a channel through the cell membrane (q.v., Figure 3) and open upon ligand binding. They are specific for certain ions, whereby Na^+- and Ca^{2+} channels have excitatory effects, due to a resulting cation influx and depolarization of the cell membrane. Inhibitory ionotropic receptors are K^+- or Cl^- channels, whereby the first group actively induces a hypopolarization of the cell membrane, whereas the latter changes the ion gradient over the cell membrane and, therefore, impedes upon the membrane's capability to depolarize.

Metabotropic receptors are bound to G-proteins (guanine nucleotide-binding proteins) on the intracellular side. Upon ligand binding, the conformational change leads to dissociation and thereby activation of the G-protein. The type of the G-protein thereby influences the actual mechanism of receptor

Figure 3 Schematic illustration of an ionotropic neurotransmitter receptor. From Cameron J. Weir. Ion channels, receptors, agonists and antagonists. Anaesthesia & Intensive Care Medicine 14 (9), 410–416. © Elsevier.

action, whereby G_i-proteins have inhibitory and G_s- and G_q-proteins excitatory effects on intracellular metabolism.

G-proteins influence the activity of enzymes, which in turn leads to a relative increase or decrease of so-called second messenger molecules. The most commonly found second messenger systems in the nervous system are the cyclic adenosine monophosphate (cAMP), the Ca^{2+}/Calmodulin (CaM), and the inositol triphosphate/diacyl glycerol (IP_3/DAG) systems.

cAMP is synthesized through adenyl cyclase (AC), whereby the G_s-protein activates and the G_i-protein inhibits AC-activity. An increase in intracellular cAMP concentration leads to the activation of a cAMP-dependent protein kinase (protein kinase A, PKA), which may either phosphorylate and thereby modify the function of ion channels within the cell membrane or alternatively phosphorylate the transcription factor CRE-binding protein (CREB) which in turn, when phosphorylated, dissociates into the nucleus and binds to the cAMP response element (CRE) within the promoter-regions of cAMP-dependent genes.

The IP_3/DAG-system is modulated through the G_q-protein, which increases the activity of the enzyme phospholipase C (PLC). PLC cleaves the membrane phospholipid phosphatidylinositol 4,5-bisphosphate (PIP_2) into IP_3 and DAG, whereby IP_3 binds and activates Ca^{2+} channels on the smooth endoplasmic reticulum, thereby increasing intracellular Ca^{2+} concentrations, and DAG activates the Ca^{2+}-dependent enzyme protein kinase C (PKC). PKC may, like PKA, phosphorylate ion channels, but also activates the transcription factors AP-1 (activator protein 1) and NF-κB (nuclear factor kappa-light-chain-enhancer of activated B cells; not only found in B cells).

Calmodulin (calcium-modulated protein) is activated by an increase in intracellular Ca^{2+} concentration, commonly either through Ca^{2+} influx via NMDA-receptors or as a secondary effect of the IP_3/DAG-system. The binding of Ca^{2+} to CaM (Ca^{2+}/Cam-complex) activates the enzyme Ca^{2+}/calmodulin-dependent protein kinase II (CaMKII) as well as PKA. Both enzymes may phosphorylate ion channels and CREB, and CaMKII presumably also activates nNOS, thereby providing the aforementioned negative feedback for NMDA-receptor transmission.

All neurotransmitters bind to receptors specific to them. The relationship between transmitter and receptor is often compared to lock and key, whereby an analogy to a locking system is more appropriate, since first, all neurotransmitters bind to several specific receptors and, second, there are usually a number of ligands besides the neurotransmitter, which bind to specific receptors. As mentioned above, these other ligands are called receptor agonists or antagonists (see below).

The nomenclature of receptors is usually achieved through numbering or alphabetizing (e.g., dopamine receptors D_1 though D_5, α- and β-adrenoceptors, or $GABA_A$ and $GABA_B$ receptors), through numbering and alphabetizing (to classify subgroups; e.g., 5-HT_{2A}-receptor) or through their primary agonist or cofactor (e.g., NMDA-receptors or muscarinergic and nicotinergic ACh-receptors).

Receptor Agonists and Antagonists; Mechanisms of Drug Action

Apart from the primary ligand, receptors are also influenced by a number of other molecules. These are usually endogenous compounds, phytochemicals or artificial chemical compounds. This can be best illustrated using the model of ACh-receptors.

Two groups of ACh-receptors exist, named after their primary agonists: The muscarinic receptor binds the phytotoxins muscarin (agonist) – named after the fungus *Amanita muscaria*, from which it was first isolated – and atropin (antagonist) – derived from *Atropa belladonna*, commonly referred to as Deadly Nightshade. The second ACh-receptor group, the nicotinic

receptor, binds nicotine (agonist) – the alkaloid found in *Nicotiana* (tobacco) and other Nightshade-species – and curare (antagonist) – a group of alkaloid poisons extracted from South American vine-species like *Strychnos toxifera*.

A number of artificial chemical compounds exist, which act through activation or blockage of a specific neurotransmitter receptor, many of which are additionally used as recreational drugs. Common examples hereof are the $GABA_A$-agonist ethanol (drinking alcohol), the NMDA-receptor antagonists ketamine (Special K) or phencyclidine (PCP, Angel Dust), the first-generation antipsychotic haloperidol (blocks, i.e., the dopamine receptor D_2), β-blockers (antagonists of the β-adrenoceptors), the $5\text{-}HT_{2A}$-agonists mescaline and psilocybin (found in 'magic mushrooms') or lysergic acid diethylamide (LSD), which activates a variety of neurotransmitter receptors, including $5\text{-}HT_3$-, $5\text{-}HT_4$-, and β-adrenoceptors.

Apart from mimicking or preventing the actions of neurotransmitters through direct interaction with specific receptors, other drugs influence neurotransmission through either inhibition of reuptake into the presynaptic terminals or through actively releasing neurotransmission by reversing the flow directions of neurotransmitter transporters and vesicular transporters.

Commonly known examples for reuptake inhibitors are cocaine (dopamine reuptake inhibitor) or specific serotonin reuptake inhibitors. Other substances, like 3,4-methylene dioxy-*N*-methylamphetamine (MDMA, Ecstasy) or the aforementioned methylphenidate (Chrystal Meth) act as neurotransmitter releasers for (in this case) serotonin and dopamine, respectively.

Finally, drug influences on neurotransmission may act in a fashion not specific to any given neurotransmitter but rather on the more basic level of inhibition of action potentials (like *Tetraodontotoxin*; e.g., from puffer fish) or exocytosis of synaptic vesicles (like *Botulinum toxin*, *Botox*).

Neutrality, Axiological

Nicholas Rescher, University of Pittsburgh, Pittsburgh, PA, USA

This article is a revision of the previous edition article by R. Fillieule, volume 15, pp. 10619–10621, © 2001, Elsevier Ltd.

Abstract

There is no way to exclude axiological considerations from scientific inquiry. For one thing, a surgical fact/value separation is infeasible on theoretical grounds. And on practical grounds, science cannot operate without a recourse to cognitive values, in particular those that distinguish the trivial from the significant. The most and best that can be done is to adopt a position of axiological neutrality that minimizes any resort to tendentious and potentially contentious evaluations in science.

Is/Ought Separation and Value Exclusion from Science

The thesis that the sciences – and the social sciences in particular – should be value free has been astir since the early twentieth century, particularly under the influence of Max Weber (see, for example, Weber, 1917). The basic idea is that scientific claims should be formulated and validated impersonally, without involving the potentially variable value orientations of different individuals. Science should deal in observable facts, with issues of value – of deservability, preferability, normativity, objection, and the like – left to individuals to resolve independently on their own. Even as physicists look to numerically accessible phenomenon ('repeatability of experiments'), so the social sciences shall look to phenomena that are universally accessible, independently of potentially idiosyncratic orientations of particular individuals or groups. To be sure, social sciences can investigate the way in which people commit themselves to values, but any and all endorsement or espousal of values is to be proscribed in this domain.

The fact/value distinction was generally drawn on essentially terminological grounds. The idea is that fact statements simply maintain what is available to observation and inference therefrom. They report on reality's descriptive makeup. Value statements, by contrast, are not factual but axiological. They have a normative and axiological dimension owing to an involvement of some evaluative terms that give expression to placement along a positive/negative, favorable/unfavorable divide. So that cats chase mice is a factual claim. That it is a good (or bad) thing that cats chase mice is evaluative. The former may be germane to science, the latter must be excluded. But unfortunately, matters are not always so clear.

It is clear that any program of value exclusion from science must be predicated from the very outset on two indispensable presuppositions: (1) that it is possible to draw a clear line of distinction between statements of fact and judgment of value and (2) that inference across the boundary between these – and in particular the demonstration of judgment of value from statements of fact – is inherently impossible. But both these contentions are very questionable.

Why Fact/Value Separation Is Untenable: I. Logical Grounds

Considerations of general principle might seem to indicate that evaluative conclusions cannot be derived for purely factual premises. For by their very nature as such, evaluative conclusions must contain some sort of value terminology, and if the premises contain no such terms whatever, then it seems plausible to suppose that there is no ground in which a validly deducible conclusion can obtain them. But what seems plausible can turn out to be false – and the present case affords an instance of this.

However, a significant stumbling block for all theories of fact/value separation is the seemingly paradoxical circumstance that (1) $F \vee V$ follows deductively from the factual premise F (and thus is itself presumably factual), while nevertheless (2) $F \vee V$ in conjunction with a factual premise (viz. not-F) yields the evaluative conclusion V (and thus is itself presumably evaluative). (This difficulty was first noted by George Mavrodes. See his essay "On Deriving the Normative from the Non-Normative" in the *Papers of the Michigan Academy of Arts and Sciences*, vol. 53 (1968), pp. 353–365.)

The only plausible response here is to abandon the idea that the logical consequence of factual statements must always be factual, and proceed to class $F \vee V$ as hybrid rather than strictly or purely factual. This done, one would continue to hold to the principle that evaluative statements never follow from purely factual ones. But on this basis, one would then have to shift from a two-sided fact/value dichotomy to a tripartite division of statements as factual, evaluative, and hybrid, and this muddies the water. For the categories of fact and value are now seen as separated not by a sharp boundary line but by a broad corridor.

Why Fact/Value Separation Is Untenable: II. Practical Grounds

Consider the following inference:

All automobiles are man-made.
Therefore: All good automobiles are man-made.

The premise of this patently valid inference is clearly factual, and its conclusion is clearly evaluative. (Observe that the

statement "Dogs chase nice cats" combined with the factual thesis "Fido is a cat" and "No dog chases Fido" entails the clearly evaluative conclusion "Fido is not a nice cat"). Does such an example not refute our thesis that factual premise does not yield evaluative conclusions?

Not quite. For closer analysis shows that what is actually at issue in the preceding inference is an enthymematic syllogism that incorporates an unstated premise:

All automobiles are man-made.
(All good automobiles are automobiles.)
All good automobiles are man-made.

And here that enthymematic minor premise can (and should) be regarded as unproblematically acceptable on grounds of its effective triviality.

Again consider the following inference:

- *X* jabbed *Y* with a needle to cause *Y* pain because *X* did not like the way *Y* looked.
- *X* had no other reason for jabbing *Y* with a needle apart from wanting to cause *Y* pain because *X* did not like the way *Y* looked.

Therefore … *X* did something wrong/wicked.

Three things are clear here: (1) the premises all state matters of fact; (2) the premises entail the conclusion; and (3) the conclusion is evaluative. So it is clear that in this as in myriad other cases, factual premises can yield an evaluative conclusion.

To be sure, a stickler might object that this inference is not strictly speaking valid though also being enthymematic. And this is true. One needs to acknowledge that the reasoning at issue is enthymematic, and requires the addition of a further premise, viz.,

(P) When a person jabs another to cause that person pain simply and solely because he or she does not like his or her looks, then this person does something wrong/wicked.

But it is clear that this further premise is trivial, self-evident, and virtually tautological given the terms of reference in which it is formulated.

In cases of this sort, where the gap between factual premises and an evaluative conclusion is so narrow that it can be filled by an effectively trivial evaluative thesis, one has a situation where the fact/value gap is effectively bridgeable.

The price of a consistent theory involves taking the not implausible line that certain evaluative truisms (such as 'All nice cats are cats') cannot but be seen as unproblematically acceptable.

And of course there will be innumerable analogous cases, for example,

- *X* had food at his disposal.
- *X* realized that *Y* was very hungry and could not otherwise obtain food.
- *X* shared his food with *Y*.

Therefore: *X* did something morally credible.

Here again, one has an effectively trivial enthymematic bridge from the factual premises to the evaluative conclusion.

When factual premises yield evaluative conclusions in the face of premises that themselves are evaluatively trivial and self-evident, one not only can but also must cross the bridge over the fact/value divide. And here it does not matter whether one is a scientist speaking ex officio or a layperson enunciating common sense.

Viewed in this light, the idea that the conscientious social scientists cannot apply evaluative labels to certain deliberations and arguments – characterizing them as unsustainable, unworkable, unduly cumbersome, or counterproductive – is clearly problematic. The economist or sociologist no less than the historian or the physician can ex officio decry various matters in negative terms without being unprofessional about it. But of course he or she can only do this unproblematically when the issue is 'plain as a pikestaff' there for anyone to see – a matter of objective conditions rather than potentially idiosyncratic personal attitudes.

The fundamental contrast, of course, should be that between what can be observed and what cannot. The value of the item is not more perceptible than is the ownership of a piece of property. But that of course does not make it something mysterious and 'nonnatural' – the special object of a peculiar detection faculty, a value intuition. Value is not sense-perceptible but mind-judgmental: something to be determined not simply by observation of some sort but by reflective thought duly sustained by background information and suitably equipped with an awareness of principles.

What Is Left of Value Freedom

It is sometimes maintained that evaluative statements cannot figure in science because they are, by their very nature, neither true nor false. But this is simply nonsense. That it is foolish never to seek the advice of a knowledgeable person, and it is ill-advised to prefer a product one deems inferior to an equally available alternative that one sees as superior. And yet such evaluative claims are clearly every bit as true as the claim that grass is generally green. Such statements obviously state facts – only evaluative facts. (Yet another nail in the coffin of an insuperable fact/value divide.) One must avoid the confusion of values and tastes. "There's no disputing about tastes" may be true, but "There's no disputing about values" certainly is not. Values too can be altogether objective, in that value claims admit of rational substantiations – through impersonally cogent considerations.

Some value exclusionists hinge their position on an is/ought divide. Science, they say, informs us about what is, leaving matters of what ought to be to others. But this does science an injustice. For science tells us not only about what is, but also about what must be if – i.e., if certain conditions are to be brought to realization. And when one inquires into the conditions that must be met to make human life (be it at the individual of scientific level) possible – or indeed even pleasant – it is to science that one will have to look.

The biochemist who discovers that a particular production process poses a clear and present environmental risk is nowise stepping outside the range of scientific propriety in disrecommending it. And the same holds for the physician who detects available risks in a certain procedure. In expressing evaluative conclusions, such people are clearly acting within the bounds of scientific propriety rather than outside it.

The preceding deliberations indicate that an impassable fact/value barrier excluding values from science must be abandoned and a different basis provided for understanding the relationship between sciences and values. This revised basis will have to lie in the idea of universality of access. For science is and should be universally available, objective and impersonal in its findings and contentions. There is no place in the rational scheme of things for an Aryan physics or a Soviet biology. And so what is in order here is a transition from the (untenable) idea of a value-free science, one in whose operations a recourse to ideologically committed and potentially debatable and divisive values has no proper place. Any value commitment – any ideologically based perspectives or doctrines – has no place in science. It is not that values are to be excluded from science, but rather that whatever values are invoked are patently cogent, and nowise debatable or divisive. The oft-claimed axiological neutrality of science is not to be grounded in its Weberian Wertfreiheit but rather in its Kantian universality.

The conclusion that follows here is thus not that science is value free – that scientists acting ex officio can and should make no evaluative claims at all. It is, rather, that such claims can unhesitatingly be made whenever they happen to be uncontroversial and uncontestable.

So what is left of the Wertfreiheit program? What remains is the ideal of value neutrality: the idea that scientists should not qua scientists proclaim potentially controvertible evaluations – that their value claims should be either substantially trivial or at least such that reasonable people cannot reasonably avoid their acceptance.

Inquiry into the conditions that make individual human life possible (and even pleasant) is clearly part of the mandate of the life sciences. And inquiry into the conditions that make collective human life in society possible and congenial is part of the mission of the social sciences. Valuation is unavoidable in such contexts, and the exclusion of valuation in such matters makes no sense here. (Evaluation plays a legitimate and constructive role even in so theoretical a discipline as pure mathematics. Here *reductio ad absurdum* serves as a standard proof technique and is predicated in the thesis that absurdity is the focus of logically demonstrable self-contradiction in something that is obviously inappropriate and unacceptable.)

In the final analysis, science cannot possibly be value free. For the assessment of importance/significance/informativeness will unavoidably have to play a pivotal role in the formulation, promulgation, and publication of scientific work. If trivial details could not be distinguished from important facts – every one factual statement on a given topic was every bit as significant as any other – no meaningful discussion could ever be managed in science nor any meaningful instruction provided.

What It Means for the Working Scientists

As these deliberations indicate, it is deeply problematic to maintain that the scientist qua scientist must refrain from drawing such normative conclusions that follow from the facts at his or her disposal in an effectively unproblematic way.

It should, however, be granted that there is one important respect in which the advocates of scientific value neutrality have it right. For what is correct is not that social sciences are value free but that any policy recommendation about social arrangements should be clear and explicit about the values that speak for its acceptance. No hidden agenda, concealed interest, correct aim, etc.

The idea is not to keep value out, but make their role overt and explicit insofar as they enter in.

For while some self-evidently incontrovertible evaluative theses have to be seen as available anytime to anyone – scientist included – nevertheless contestable and potentially idiosyncratic evaluative claims are something else again.

So in the end, there are two distinct albeit related positions. One is based on the problematic but essentially factual idea of value exclusion from sciences predicated on the thesis that a Chinese wall of sorts exists to separate factual from evaluative claims. The other is based on the essentially normative idea that a scientific exposition should be candid and explicit about any operative value commitments in the interests enabling the neutrality of letting people form their own conclusions and averting a situation where advocacy wears the sheep's clothing of informativeness. Patently contestable value endorsements have no place in science. In this regard, science should be value neutral. There is – to reemphasize – no place for a Soviet biology or a Germanic physics.

The present article has argued that the first of these two positions is untenable and should be rejected but that the second is very much in order. On this perspective one cannot invoke an absolute fact/value divide to exclude evaluative claims from bearing any and all place in scientific deliberations. Rather one has to retreat to the position that what is questionable in science is significantly substantive and thereby potentially divisive evaluative claims.

Two decidedly different positions with respect to value freedom are at issue here. One is the problematic idea of value exclusion pivoting on that the sciences are altogether factual and have no evaluative or normative involvements. The other is the sensible and appropriate doctrine of value neutrality, viz., that the sciences properly should take sides on tendencies substantively controversial evaluative positions.

And this situation has important implications. For in many instances, the idea that a certain interaction is uncontestable and noncontroversial in itself is something that can be called into question. And this means that whenever there is even a remote chance of this, a scientist must be very clear and explicit about it so that his or her audience can judge matters for itself as regards the acceptability of the value claims at work. Just as the legislator should 'declare an interest' in an issue mode discussion, so the scientist should 'declare a normative commitment' in matters of deliberation.

The fallback from value exclusion to value neutrality is an important and well-advised step. For as Leo Strauss has rightly argued against the Weberian proscription of valuation in science, if there were no evaluative facts, then all evaluations would become arbitrary and unsustainable (see Strauss, 1953). And then if one scientific statement is no more important than another, one scientific claim no more reasonable than another, one scientific recommendation no more acceptable than another, and the ability and value of science itself

will be compromised beyond reason. If one claim is no more rationally appropriate than another, then where does that leave science itself? Valuation in science and valuation by science are essential aspects of overall functioning of our scientific endeavors.

In the final analysis, there is something rather self-inconsistent about the advocacy of value exclusion from science. For, of course, it is only possible justification of this contention would issue from a contention along such social lines as "Staking evaluative claims in the social sciences is inappropriate because doing so does disservice to the prospects of realizing the proper aims of the enterprise – viz. achieving a deepened explanatory understanding of social phenomena." But the fusion of factual and evaluative considerations in this claim itself is unmistakable the very surface of it.

New Genetics and Race

Yulia Egorova, Durham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores the way notions of race and ancestral origins are constructed in recent research in population genetics. The author focuses on studies used in health care, in the criminal justice system, and in genetic history. The article demonstrates how contemporary genetic research employs preexisting categories pertaining to race and descent, and discusses what implications it has had for processes of identity construction.

What is the relationship between genetic research and constructions of race? What contribution have geneticists made to the study of 'human genetic diversity'? What assumptions about the way humanity can be divided into distinct populations inform theoretical and methodological thinking, which in turn underpins research in the life sciences? Finally, in what ways has genetic research been used by the communities that it has researched, and by other stakeholders outside of the world of science? The author explores these issues by looking at literature within the social sciences and humanities addressing the sociocultural and political implications of genetic research. For the purpose of this analysis, the author divides the discussion of this field of literature along two main thematic lines. First, the author discusses studies that have focused on the role that genetics plays in categorizing humans into distinct populations either for medical purposes or for use in the criminal justice system. Second, the author explores genetic research initiated for the purposes of reconstructing the history of human migrations. In each case, the author focuses both on the genetic studies themselves and on their reception by the tested communities. In the end, the author discusses the way population genetics has been used to advance what has been described as 'genomic sovereignty' in countries and communities located outside Europe and North America.

Genetics and Race Revisited

In a seminal paper published in 1972, Richard Lewontin demonstrated that the major part of human genetic variation occurred among individuals within local geographic populations, which suggested that the concept of race was an invalid taxonomic construction (1972). The same idea was promoted by Luigi Luca Cavalli-Sforza, the initiator of the Human Genome Diversity Project (HGDP), which was supposed to map gene distributions of different populations around the world. The HGDP was launched almost in opposition to the Human Genome Project. Its initiators argued that the Human Genome Project did not take into consideration the diversity of human populations all over the world. They endeavored to fill this gap by collecting, preserving, and analyzing the DNA from about 500 populations around the globe that had been geographically isolated and had a distinct culture and language, as these would yield more information than genetically mixed urban ones. The collected materials were planned to be made available to scientists and scholars worldwide for research on the history of human migrations and biology (M'charek, 2005: pp. 6–7). The project initially received positive coverage in journals such as *Science* (e.g., Kahn, 1994: pp. 720–723) and was endorsed by the Human Genome Organisation. However, the HGDP soon ran into trouble, as its initiators were accused of exploitation and even racism (Haraway, 1997: pp. 248–253; M'charek, 2005: pp. 5–16; Marks, 2003: pp. 198–219). The accusation may seem surprising, given that one of the conclusions drawn by Cavalli-Sforza was that the notion of 'race,' which figured prominently in the scientific, historical, political, and popular discourses of the previous two centuries, had no genetic basis and that genetic differences that existed between any two individuals were vastly more significant than those between any two populations (Cavalli-Sforza, 2000: viii). Although such conclusions appear to be a powerful weapon in the struggle against racism, it has nevertheless been suggested that the HGDP and similar studies construct biological differences between various human populations: Cavalli-Sforza's endeavor may have thus helped to debunk the idea of dividing humanity into a limited number of major races, but it reinforced the notion that individuals could be divided into discrete populations on the basis of their genetic makeup. (For a critical discussion of the HGDP see M'charek, 2005; Reardon, 2005.)

It has been argued by commentators in the social sciences that this type of research in population genetics is permeated by 'racialist' thinking. (For a discussion of the distinction between racism and 'racialist' (or race) thinking, see (Skinner, 2006: p. 483). Indeed, some scientists have suggested that race is a useful operational category in genetic research and is of medical relevance, while the evolutionary biologist Armand Leroi (2005: p. A23) went as far as to declare that 'races clearly exist' and that 'the consensus about social constructs is unraveling.' For a very useful analysis see Hartigan (2008, 2010). For a discussion of internal debates among scientists about the usefulness of the term 'race' see Fausto-Sterling (2004).) Moreover, as Veronika Lipphardt has argued, drawing on Nancy Stepan (2003), any attempt to produce 'scientific facts' about human biological diversity is grounded in political agendas and social tensions (2012: S69). The way the categories of race and ethnicity are institutionalized and naturalized in population genetics has been discussed in a number of ethnographic studies of scientific practice (Reardon, 2005; M'charek, 2005; Fullwiley, 2007a,b). Duana

Fullwiley (2007a), for instance, has demonstrated in her analysis of two laboratories of pharmacogenetics that even though researchers themselves may struggle to define race and even have negative personal experiences of having to 'fit' their own identity into the predetermined categories of the US 'race and ethnicity' questionnaires, they still comply with the established practice of defining and comparing US groups in their work. It has therefore been demonstrated that the process of looking for genetic differences between populations is mediated from the outset by preexisting historical and sociocultural ideas about collectives of individuals constituting separate populations that are supposed to differ from each other on the level of biology. As sociologist of science, Troy Duster notes:

> It is possible to make arbitrary groupings of populations (geographic, linguistic, self-identified by faith, identified by others by physiognomy, etc.) and still find statistically significant allelic variations between those groupings. For example, we could examine all people in Chicago, and all those in Los Angeles, and find statistically significant differences in allele frequency at *some* loci (2003: 265).

Race, Genetics, Crime, and Medicine

What are the practical implications of population genetic research? In what ways has it been used 'on the ground'? First, it appears to be increasingly deployed in the name of improving health care provision in general and for 'minority' groups in particular. Some studies have aimed to include underrepresented communities in clinical trials to ensure that medical research does not rely entirely on people of European descent, or otherwise run the risk of jeopardizing 'minority' communities' chances to receive adequate pharmaceutical care. Social scientists have discussed the advantages and disadvantages of this approach pointing both to its practical, medical, and broader, ideational implications. Steven Epstein has suggested that this is "a victory worth savoring in a long struggle to bring medical attention to the excluded and underserved" (2007), but has also cautioned that this approach could reinforce racial categorization.

Other projects have attempted to seek a genetic basis for diseases and conditions with higher prevalence among particular populations. For instance, there has been a steady interest in connecting heart disease and hypertension in African-Americans to the genetics of 'race,' despite existing evidence that these complex conditions are associated with poverty and stress, among other factors, which could also explain why they are common in a community suffering from structural inequalities (Duster, 2003, 2005; Kahn, 2004). More specifically, in 2005, the Food and Drug Administration in the United States approved BiDil as a drug to treat heart failure specifically in African-Americans. As Jonathan Kahn has demonstrated, this was 'part of a much larger dynamic of reification in which the purported 'reality of race' as genetic may be used to obscure the social reality of 'racism,' including the health inequalities that map onto racial discrimination (Kahn, 2011: pp. 139–140).

Some genetic research has focused on groups that are at higher risk of recessive diseases, particularly Tay-Sachs disease, sickle-cell anemia, and cystic fibrosis (for a historical discussion see Wailoo and Pemberton, 2006). Such studies have undoubtedly contributed to a better understanding of these conditions and in some cases were even used by the 'affected' communities to improve health care provision for their members. For instance, an Orthodox Jewish group in the United States made use of research on Tay-Sachs disease to organize premarital genetic screening for their young men and women (Wailoo and Pemberton, 2006: pp. 17–20). However, it was pointed out that the danger of this type of research is that it opens the way for stigmatization of groups where a recessive condition is found at higher frequency. As Wailoo and Pemberton observe, the emergence of these conditions in the public consciousness in the United States transformed them into "vehicles for thinking about race and ethnicity" (Wailoo and Pemberton, 2006: p. 10). Not surprisingly, some communities protested against being associated with a genetic disorder. For instance, Ashkenazi Jewish women expressed concern about being identified as 'at risk' populations for breast cancer (Duster, 2003). Many African-Americans were wary of genetic screening and counseling for sickle-cell anemia, which for them had associations with the disturbing history of racial discrimination in the US health care (Wailoo and Pemberton, 2006).

Concern about racial discrimination has also been raised with respect to the use of DNA in the criminal justice system. It has been convincingly demonstrated that DNA databases used in the criminal justice systems in different countries around the Western world contain a disproportionate amount of DNA from people coming from 'minority communities' (Washington, 2010). Helen Wallace observes that in Britain, home to the largest DNA database in the world in terms of the proportion of the DNA samples of the population that it contains, "[a]pproximately 27 percent of the entire black population, 42 percent of the male black population, 77 percent of young black men, and 9 percent of all Asians have records on the National DNA Database, compared with just 6 percent of the white population" (2011: 76). Moreover, it has been reported that "an estimated 55 percent of those from black and minority ethnic communities who have their details on the database have never been charged or convicted of any offense," she notes (Wallace, 2011: p. 76). Similarly, Michael Risher has discussed how in California the retention of arrestee's DNA has led to the magnification of the racial disparities that had already been present in the criminal justice system of the state (2011: p. 47).

Genetic History

Studies in population genetics that concern themselves not with health care but with reconstructing the history of human migrations have also attracted a considerable amount of critical attention in social sciences. Such studies, which are sometimes referred to as genetic anthropology, anthropological genetics, or genetic history, constitute an important fraction of the growing body of population genetics. (For an excellent historical discussion of the emergence and early development of the field, see Sommer, 2008.)

This type of science is oftentimes described as 'genetic carbon dating,' as it is supposed to facilitate historical research, which otherwise would allegedly lack adequate tools for deciphering human past. As geneticists Mary-Claire King and Arno Motulsky put it, "the DNA of modern humans contains a record of the travels and encounters of our ancestors" and furthermore that

> The genotypes of people living today are the result of ancient human migrations, selection by climate and infection for genetic alleles that conferred a survival advantage, and mating patterns determined by cultural norms. By sampling genotypes from people across the globe, geneticists have reconstructed the major features of our history: our ancient African origin, migrations out of Africa, movements and settlements throughout Eurasia and Oceania, and peopling of the Americas. (quoted in Davis, 2004: p. 41)

To name just some such studies that specifically aimed to shed light on the processes of the formation of particular communities and thus to contribute to historical debates, one could refer to research on the ancestry of African-American and Native American groups and on different Jewish communities around the world.

One of the projects on African-American ancestry was launched by Rick Kittles then based at Howard University (Sabeti, 2002). The project was supposed to allow African-Americans to trace their ancestry to a particular region in Africa. Kittles argued that it could help this community to find out where exactly their ancestors were from. In addition, it was argued that such tests might turn out to be a very useful historical tool, as research on African-American roots was often limited due to lack of documentation. However, Kittles admitted that in some cases these tests could have a disruptive potential if their results contradicted family lore (see Sabeti, 2002). Other commentators have observed that this type of research has a danger of dividing African-Americans and distracting them from campaigns to improve the social and economic conditions of their community (Dula et al., 2003).

Similarly, there have been a substantial number of genetic studies addressing the origin of various Jewish groups. Perhaps the most widely publicized of these were the studies carried out on the *Cohanim* (Jewish priests) and on the origins of the Lemba Judaising group of southern Africa (Spurdle and Jenkins, 1996; Skorecki et al., 1997; Thomas et al., 1998, 2000).

The latter represent an example of a group whose communal narrative has been strengthened by genetic findings. (For a detailed discussion see Parfitt, 2002, papers by Azoulay, Johnston, Parfitt, and Zoloth in *Developing World Bioethics*, 2003, 3 (2), and Parfitt and Egorova, 2006.) In other cases, traditional creation stories have been threatened by genetic research and could even have negative practical outcomes. For instance, as Vine Deloria (1995: p. 82) observes, studies on Native American communities supporting the dominant story of the migration of their ancestors from the Bering Strait, promote the idea that Native Americans were not the original inhabitants of North America but 'late comers who had barely unpacked before Columbus came knocking at the door.' Problematically, the more Native Americans are seen as 'recent immigrants' the weaker their claims to land and sovereignty (Davis, 2004: p. 42). It has been pointed out that potential risks and benefits of this type of research go far beyond the individuals who actually agreed to take part in it and pertain to the group as a whole, which means a necessity for developing procedures for obtaining collective informed consent (Reardon, 2005; Widdows, 2007). However, the problem of seeking communal consent is complicated by the fact that the groups whose interests are concerned in these studies may be very diverse. As Davis (2004: p. 41) has put it, "a creation story that is a source of power for one subgroup may serve to marginalize another subgroup." (For further discussion see Brodwin, 2002; Elliott, 2003; Johnston 2003.)

Discussion

Scientists involved in such studies tend to portray their work as a neutral and objective contribution to historical research, a novel way of doing history by using 'superior' methods of genetics. Nevertheless, scholars coming from the perspective of social sciences and humanities disciplines have suggested that studies in genetic history indicate a worrying trend in DNA research, as they appear to naturalize social and cultural differences (e.g., Simpson, 2000; Abu El-Haj, 2007; Abu El-Haj, 2012; Palmie, 2007; Palsson, 2007; Reardon, 2005; Skinner, 2006; Smart et al., 2008).

A number of social scientists have paid particular attention to the way genetic anthropology has engaged with issues of personal and communal modes of self-identification, narratives of origin, and notions of relatedness. It has been lucidly demonstrated that such DNA studies are often informed by preexisting cultural and political discourses about the meaning of histories that they endeavor to reconstruct, and that in the imagination of the tested and their 'observers' the genetic markers 'assigned' to populations in the course of this kind of research are likely to be reinscribed as markers of social identification. To give an example related to genetic research on Jewish communities, Nurit Kirsh has argued that Israeli scientists involved in such studies in the 1950s almost unconsciously internalized Zionist ideology, which found expression in their work trying to prove the 'common origin' of various Jewish groups around the world (2003). Nadia Abu El-Haj cites the example of genetic research on the Lemba – a Judaising group in southern Africa, whose claims to Jewish origin have received a 'positive' response from geneticists, and suggests that the genetic study that established a 'biological' connection between the Lemba and the Jews has paved the way for their recognition by a number of Jewish organizations and educational charities (Abu El-Haj, 2012). (For a detailed analysis of genetic research on the Lemba see Parfitt and Egorova, 2006.)

At the same time, other commentators have pointed out that this 'new' genetic knowledge hardly superseded communal traditions or led to the emergence of new forms of belonging that would be completely at odds with those already in existence. Thus, Nikolas Rose suggests that "ideas about biological, biomedical, and genetic identity will certainly infuse, interact, combine and contest with other identity claims," but they can hardly be expected ever to supplant them (2007: p. 113).

Alondra Nelson in her study of the genetic ancestry tests offered to African-American and Black British citizens has convincingly argued that those who order these tests in an attempt to establish which part of Africa their ancestors may be from do not accept the results at face value but reinterpret them in light of their own 'genealogical aspirations.' Nelson therefore suggested that "while the geneticization of race and ethnicity may be the basic logic of genetic genealogy testing, it is not necessarily its inexorable outcome" (2008: p. 761). Reflecting on the role that genetic anthropology has played in such projects in the construction of collective and individual pasts, Marianne Sommer has observed that "[w]e have only just begun to understand the complex processes at work when DNA technologies enter into cultures of remembrance. Nonetheless, our current knowledge points towards the importance of the history and diversity of these cultures for the ways in which communities may or may not come to (re) imagine themselves in terms of new genetically based histories and in relation to biosocialities, which may or may not (re) form around genetic markers of ancestry" (2010: p. 387).

To return to the context of genetic research on the Jews, it has also been noted that it is too early to suggest that genetic constructions of a common Jewish origin are superseding other definitions of being Jewish. Thus, Barbara Prainsack and Yael Hashiloni-Dolev have argued that new 'discoveries' in 'Jewish genetics' have mostly remained without any political or practical consequences (2009). It has been demonstrated that in the case of the Lemba, as well as of some other 'emerging' Jewish communities, 'DNA evidence' did not play any role in defining their *halakhic* status (Halakhah is collective body of Jewish religious law) or their eligibility to the State of Israel (Parfitt and Egorova, 2006; Prainsack and Hashiloni-Dolev, 2009; Egorova, 2009a). Similarly, it has been demonstrated in relation to genetic research that engaged with the history of the caste system that, although 'DNA evidence' is widely used by 'lay commentators' as a rhetorical means for inscribing identities, it is often used selectively to support the more favored accounts about the origin and historical development of different groups. First, it was shown that genetic studies themselves offer different accounts of early Indian history: just like the explanations about the origin of the caste system provided by earlier commentators – from colonial scholars and administrators to Hindu reformers and nationalists were diverse – recent genetic studies have offered conflicting inferences on the nature of castes and tribes of the subcontinent. The models for the history of caste formation offered by geneticists were in their turn used by different social groups selectively in order to strengthen their own political agendas and to assert preferred identities (Egorova, 2009b). It could therefore be suggested that the interest that communities have expressed in embracing 'genetic history' indicates that while accepting its biological determinism, they also perceive it as imbued with liberatory potential (Egorova, 2009, 2010). Moreover, depending upon the specific social and political contexts in which genetic studies are commissioned, performed, and interpreted, their outcomes may have differing degrees of significance for the tested. As Sommer has argued in the context of her analysis of genetic ancestry testing in Switzerland, "there are people who perceive the genetic analysis as a new tool for self-(re)fashioning, and there are those whose (national) histories are controversial and for whom the genetic determination of origins and history becomes a serious arbiter in identity politics" (2012: p. 135).

Finally, the context that in recent years became particularly relevant to the discussion of the political significance of population genetics is that of biotechnology research in postcolonial world. It has been observed that genomics and biotechnology have become a measure of political and economic success for any country in the twenty-first century. (For an excellent discussion of the principle's applicability in 'non-Western' contexts see Ong, 2010; Sunder Rajan, 2006.) Therefore, it is not surprising that more and more governments outside Europe and North America are prepared to invest significantly in the development of the life sciences in an attempt to establish what has been described as 'genomic sovereignty' (Benjamin, 2009). Although these policies are designed to promote academic and economic independence for 'local' hubs of science and technology, they are also embedded in the global networks and processes of knowledge production. They 'naturalize' national populations in the name of postcolonial empowerment, but at the same time borrow practices and conceptual tropes from the wider context of 'genetic labeling' to reinforce already existing categories (Benjamin, 2009: p. 342).

To conclude, as Schramm, Skinner, and Rottenburg have put it, "The new genetics is part of changes that have a direct bearing on the notions of self and relatedness" (2012: p. 2). It is not at all surprising then that the new genetics was bound to introduce new dimensions into public, academic, and political discourses about the constructions of race and identity with the potential to reinstate old stereotypes and imbue them with new meanings, to continue the cultural work that was started by biological research of the past, and to add to it new complexity.

New Institutionalism in the Analysis of Complex Organizations

Walter W Powell, Stanford University, Stanford, CA, USA
Patricia Bromley, University of Utah, Salt Lake, UT, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The new institutionalism in sociology and organizational research is best represented as an extended family of scholars that share a broadly defined theoretical orientation. The multiple lines of thought in this tradition have a common interest in the relationship between social structure and organizations. Within this frame, researchers differ in their conceptualization of institutions (e.g., as specific legal or resource relationships versus a wider culture), the focus of causal arguments (e.g., top-down versus bottom-up), and the focal feature of organizations (e.g., formal structures versus practices and behavior). This robust theoretical tradition provides a valuable lens for understanding contemporary organizations and management.

Introduction

An institutional turn has taken place across the social sciences, with active strands arising in economics, political science, and sociology. In economics, rational choice institutionalism emphasizes coordination mechanisms that solve collective action problems by generating new forms of commitment and rule-following or norm-abiding behavior. Historical institutionalism, a cornerstone of comparative politics research, underscores how institutions emerge from and are embedded in temporal processes through path dependence and divergence at critical historical junctures. Sociological institutionalism shares this general emphasis on the influence of broader social structures, but takes a more cultural view of institutions, highlighting their role in providing models or scripts for action. We would not be the first to paraphrase former President Richard Nixon and argue: 'We are all institutionalists now.' In this article we focus on the sociological stream of new institutionalism, which has become particularly dominant in contemporary organization and management theory.

The Foundations of Sociological Institutionalism

In early analyses of the process of institutionalization – the 'old' institutionalism, if you will, scholars such as Selznick, Zald, and Clark explored how the policies and routines of a particular organization acquired local resonance and became self-sustaining. Selznick (1949) famously documented how the Tennessee Valley Authority (TVA)'s efforts to coopt grass-roots agrarian groups succeeded, and the resulting accommodations eventually took on a life of their own, supplanting the TVA's original purposes. Institutionalization, in Selznick's (1957: p. 17) eyes, refers to the process whereby practices become 'infused with value beyond the technical requirements of the task at hand.'

In contrast to this initial focus largely on internal organizational dynamics, a 'new' institutionalism shifted attention outward to examine how the external environment socially constructs organizations, providing them with templates for their formal structures and policies, and thereby increasing an organization's legitimacy in the wider world. New institutional studies of organizations in the 1970s and 1980s are largely characterized by emphases on diffusion, isomorphism, and decoupling. As put by DiMaggio and Powell (1991: p. 8): "The new institutionalism in organization theory and sociology comprises a rejection of rational–actor models, an interest in institutions as independent variables, a turn toward cognitive and cultural explanations, and an interest in properties of supraindividual units of analysis that cannot be reduced to aggregations or direct consequences of individuals' attributes or motives."

In a foundational paper, Meyer and Rowan (1977) set out a view of complex organizations in postindustrial society as reflecting wider myths in the institutional environment rather than the technical demands of production. In order to protect an organization's technical core, they posited a great deal of decoupling between espoused policies and actual practices, as well as internal buffering among subunits. Further, as the environment impinges on organization, considerable homogeneity among organizations develops in their formal structures, beyond any internal technical needs. Drawing on work in social psychology, Zucker (1977) emphasized that institutionalization is an organizational level process, and viewed diffusion as a consequence of institutionalization rather than a cause. Echoing this emphasis on mechanisms, DiMaggio and Powell (1983) brought causal force to the processes of diffusion and isomorphism by spelling out mimetic, normative, and coercive channels through which ideas and practices flowed. In so doing, they emphasized the important roles of the professions, higher education, and media in promulgating ideas and projects that are widely incorporated by modern organizations. In a subsequent article, DiMaggio and Powell (1991) drew on Bourdieu, Goffman, and ethnomethodology to fashion a theory of practical action, in an effort to build linkages between internal organizational routines and habits and macrosocial forces.

Even among these early studies, it is perhaps more appropriate to think of related lines of inquiry, rather than a unitary conceptual paradigm. Institutionalism in organization theory is a big tent, in which scholars share a general conception of institutions as having normative, cultural, and regulative elements (Scott, 2001). But under the broad canopy of

attentiveness to external institutional influences, scholars differ in both their conceptualization of institutional environments and in the extent to which individuals and organizations are seen as being fundamentally shaped *or* constituted by the external environment. At the most constructivist end of the continuum, John Meyer and colleagues emphasize the social creation of actors themselves (Meyer, 2010). In this view, individuals and organizations are constituted by their environment. At the other end of this spectrum are depictions of entrepreneurs pursuing self-determined interests within a set of institutional constraints and supports, and in so doing building or cocreating institutions (Battilana et al., 2009; Lawrence et al., 2009).

The conceptual breadth of the new institutional family, and the productive conflicts among its variants, contributes to the theory's ongoing intellectual vibrancy and growth. Older divisions over agency and power continue, but at least since the 1990s new debates have come to the forefront. First, recent scholarship has extended Zucker's (1977) emphasis on the microfoundations of institutional processes, bringing greater attention to the linkages between individuals and institutions. Second, others seek to move away from a focus on isomorphism and toward institutional sources of heterogeneity (Greenwood et al., 2011), most notably through ideas of institutional logics. A Scandinavian strand of work emphasizes translation and editing, recognizing that as institutionalized practices flow around the globe, the nature of reception and adoption often reflects strong local contingencies (e.g., Brunsson and Jacobsson, 2000; Czarniawska and Sevón, 1996). Others have reconceptualized theories of loose coupling (Bromley and Powell, 2012). Third, in macrolevel research, Meyer and Rowan's early insights about organizations have been extended globally, creating a stream of research known as world polity or world society theory. In what follows we discuss developments in new institutional theory in each of these areas since the 1990s.

Microfoundations: How Are Institutions Formed and Reproduced?

Overview

Initial work on microfoundations was prompted by a recognition that macrolines of research could profit from a micromotor. Such a motor would involve theories that attend to enaction, sensemaking, and meaning. Institutions are sustained, altered, and extinguished as they are enacted by individuals in concrete social situations. This line of work is guided by an effort to understand how individuals locate themselves in social relations and interpret and respond to their institutional context.

Institutional forces shape individual interests and desires, framing the possibilities for action and influencing whether behaviors result in persistence or change. Macroinstitutional effects create conventions that are the scripts for meaning making. This process is recursive and self-reinforcing. Powell and Colyvas (2008) lamented, however, that the individuals that populated much of institutional analysis were portrayed as either 'cultural dopes' or heroic 'change agents.' Moreover, too many analyses conflate macrofactors with structural forces and assume these factors only reinforce stability and homogeneity, while associating microfactors with entrepreneurship and agency. But individuals also play an important role in inhabiting institutions (Hallett and Ventresca, 2006), and organizations can serve as entrepreneurs. Moreover, macrotrends, such as globalization, can be profoundly destabilizing to local orders and individuals. Clearly, it is a mistake for institutional analysts to blindly equate change with the microlevel and persistence with the macrolevel.

Contributions

Institutions are reproduced through the everyday activities of individuals. Members of organizations engage in daily practices, discover puzzles or anomalies in their work, problematize these questions and develop answers to them by theorizing them. In turn, participants ascribe meaning to these theories and, in so doing, develop and reproduce taken-for-granted understandings. Jepperson (1991) was one of the first to emphasize microtranslation – an understanding of how macrocategories get inside the heads of individuals. Macroframings or values can be 'pulled down' to the everyday level of practice, as varied activities can be pursued under a common interpretation or account, or diverse practices can be pursued in the search of a common goal (Colyvas and Powell, 2006). Many microprocesses represent local instantiations of macrolevel trends. DiMaggio and Powell's (1991) overview of the elements of a theory of practical action similarly focused on microtranslation. Responding to readings of their 1983 article that contended that mimetic and normative isomorphism entailed 'mere' copying and replication, they emphasized that practical consciousness involves energy, effort, and reflection. DiMaggio and Powell argued that habitual action does not reflect passivity, but is a skilled means of directing attention. Everyday reasoning requires individuals to negotiate rules and procedures flexibly and reflexively to assure themselves and others around them that their behavior is sensible.

In a wide range of empirical ethnomethodological studies, categories and classifications become interpretive schema that members of organizations draw on. Over time, these schemas become a repository of organizational knowledge. As particular schemas become routinized through repeated application and use, they develop a habitual, taken-for-granted character. Berger and Luckmann (1967) emphasized that once joint activities are habitualized and reciprocally interpreted, patterns both harden and deepen as they are transmitted to others, particularly newcomers. When schemas become perceived as objective, exteriorized facts, their contingent origins are obscured.

Ethnomethodologists have demonstrated how classifications and categorizations are invoked on the fly by skilled actors to keep peace on the streets, in the courts, in hospital wards, and welfare agencies. Rather than struggling with or coping with uncertainty, the practical reasoning view emphasizes how situations are rendered comprehensible, and sees such efforts as an ongoing, contingent accomplishment. This is in contrast to a Weberian view of the typical bureaucracy more as a target or ideal. For the ethnomethodologists, bureaucracy

is neither a rarified nor lofty goal, but deeply embedded in commonsense routines of everyday life. Organization is a formula to which all sorts of problems can be brought for solution.

A related line of microresearch builds on ideas involving sensemaking, associated principally with Karl Weick (1995). Sensemaking is inherently retrospective and precedes action because situations are only understood upon completion. Meaning is shaped through attention to what has already occurred, and is therefore directed, not attached, to action. Because outcomes and subjective objects are implicit in interpretation, sensemaking entails a process that simultaneously enacts identity and institutions. Identity is central because individuals act based on who they are, not on what choices they have, and this feature is constituted out of the process of interaction. Mead's (1934) insights that each individual is a 'parliament of selves' and that 'social processes precede the individual mind' are critical. The environment is not viewed as a fixed and stable reality, but as a coconstruction of individuals' minds and their actions. Enactment represents the reciprocal interaction of the material and the cognitive world.

A sensemaking approach directs attention to the importance of language, routines, and communication for analyzing microprocesses. While emphasizing that various institutional materials are commonly 'pulled down' by individuals and translated within organizations, these processes may differ across circumstances. Multiple modes of meaning-making occur at the interface of identity and the enacted environment, and how such understandings are forged and enacted occur through retrospection. Sensemaking is thus a key micromechanism of institutionalization that allows consideration of both the 'cognitive complexities' that guide organizational behavior and recognition of the varied ways that institutionalized practices operate at the microlevel (Jennings and Greenwood, 2003).

Over the past decade, a new group of institutional scholars seeking to explain how extant institutional arrangements are altered have turned to the concept of institutional entrepreneurship, as highlighted by DiMaggio (1988: p. 14): "New institutions arise when organized actors with sufficient resources (institutional entrepreneurs) see in them an opportunity to realize interests that they value highly." The concept of institutional entrepreneurs was first developed by Eisenstadt (1980) in his work on Weber's concept of charisma, where he studied rare, but epochal, individuals who sparked institutional change. These are creative individuals whose social positions and skills allow them to recognize problems or opportunities and take advantage of enabling conditions to alter the social order (Battilana et al., 2009).

Work on institutional entrepreneurship has emphasized the microlevel processes through which intentional institutional change takes place, including acts of convening, the framing of projects, the process of mobilizing resources, and the binding of new practices and forms to extant institutions (Hardy and Maguire, 2008; provide a good overview of these studies). Such work has shed light on processes of organization-building and other kinds of institutional innovation that went largely unexamined in early studies.

Challenges

Discussions of microtheories that portray individuals and institutions as mutually constitutive are useful, but this work remains fairly conceptual and, thus far, lacks rich empirical grounding. Indeed, it is unclear at this stage how such work could be conducted, outside of detailed ethnographic study. Work on institutional entrepreneurship represents an effort to replace the imagery of oversocialized individuals, slavishly devoted to habits and fashions of the day. But the new celebration of entrepreneurs has possibly gone too far, as not all changes are led by purported entrepreneurs. A further limitation of work derives from the relatively short temporal frame covered by most studies of institutional entrepreneurship, which regularly slice historical processes that are unfolding on the scale of many decades or even centuries into very short time periods. Thus, critical macrolevel processes remain obscured from analytical view, especially when they are taking place beyond the immediate fields under investigation. Against this relatively static backdrop, the 'embedded agency' of individual institutional entrepreneurs can loom artificially large. Moreover, because the cases studied have almost exclusively involved successful projects, it has been tempting for researchers to seek out confirming signs of 'heroic' contributions to observed outcomes. This sampling on the dependent variable renders any possibility of generalization moot.

Crossing Levels: Institutional Logics

Overview

Scholarship on institutional logics focuses on how competing societal level belief systems shape both individuals and organizations. This stream of research focuses on the effects of distinct and diverse institutions in influencing behavior inside organizations. Thornton and Ocasio (2008: p. 99) suggest that: "By providing a link between institutions and action, the institutional logics approach provides a bridge between macro-/ structural perspectives and more micro-/ process approaches." The institutional logics perspective has proven valuable for spurring research on three fronts: change, complexity, and practice variation.

Thornton and Ocasio (2008: p. 101) developed a widely used definition of institutional logics as 'the socially constructed, historical patterns of material practices, assumptions, values, beliefs, and rules by which individuals produce and reproduce their material subsistence, organize time and space, and provide meaning to their social reality.' Heavily influenced by Friedland and Alford's (1991: p. 232) depiction of five key institutions – the capitalist market, bureaucratic state, democracy, nuclear family, and Christianity, each guided by a distinctive modus operandi, this approach sees change originating from contestation between rival logics. A more recent formulation of the interinstitutional system retains this macroemphasis, but melds the operational and ideological elements of institutions (e.g., the bureaucratic state versus democracy) and expands the application of the logics perspective beyond Christian and democratic countries (Thornton et al., 2012). The authors identify six distinctive societal institutions – the market, the corporation, the

professions, the state, the family, and religions. Within each of these metainstitutions, there are differences – in the sources of legitimacy, authority, and identity; basis of norms, attention, and strategy; informal control mechanisms; and economic rewards. Each societal sector is linked to a specific logic that shapes its material practices and organizational forms. There is much in common here with recent French social theory on different orders of worth, see particularly Boltanski and Thévenot (2006), though these parallels have not been pursued.

Contributions

The concept of logics has been valuable in depicting social transformations. Much research has focused on either a shift from one dominant logic to another, or the layering of multiple logics. Scott et al. (2000) detailed how the growth and expansion of new logics in healthcare led to the valorization of different actors, behaviors, and governance structures. Even as doctors and their patients were replaced by healthcare providers and consumers, they stressed that professional, bureaucratic and market logics intermingled, with one supplanting though not eliminating the other. The central idea is that institutional logics focus the attention of key actors on a particular set of problems and solutions. Changes in observed material practices and meanings can reflect movement between institutional logics.

Research on logics also provides a way for examining complexity, pluralism, and heterogeneity. Friedland and Alford's (1991) initial conception of logic was intended to describe competing and even at times contradictory practices and beliefs in modern Western societies. The tensions inherent in different logics provide the resources for individuals and organizations to transform social practices and structures. By focusing on how some fields are composed of multiple logics, and thus, varied forms of institutionally based rationality, institutional analysts offer new insight into practice variation and the dynamics of adoption. Multiple logics can create diversity in practices by enabling variety in cognitive orientations, prompting contestation over which practices are appropriate. These contradictions in multiple logics can also create ambiguity, leading to logic blending, the creation of new logics, or the continued emergence of new variants. This revision to a theoretically abstract and analytically distinct set of ideal types makes it useful for studying multiple logics in conflict and consensus, the hybridization of logics, and institutions in other parts of society and the world. This perspective emphasizes heterogeneity, whereas the earlier macroinstitutional perspective focused on similar changes across differentiated sectors that are attributed to one master form of rationality.

Challenges

Despite its benefits for understanding change, complexity, and practices, the institutional logics perspective is not without challenges. One issue lies in the source of logics. Where do they come from? Why these six? Do they operate with differential force, in different social settings? When and why is conflict among logics provoked? It is often not clear why actors begin to prefer one logic over another, thus much of the research is more descriptive than explanatory. (For a very different causal account of how distinctive roles and networks prompt conflicts and generate novelty, see Padgett and Powell, 2012.) A second criticism lies in ambiguity with the term 'institutional logic.' The definition put forth by Friedland and Alford (1991), as well as Thornton et al. (2012), is tied to megastructures in society, but at times the phrase is disconnected from the macrointerinstitutional system and used to describe nearly any moment of conflict or complexity, such as clashes between departments or individuals over 'love or money.' When microlevel observations are not linked back to the larger structures of society it is unclear what is particularly institutional about the arguments or what the larger logic involved may be.

Macrolevel: World Polity

Overview

Whereas the logics perspective emphasizes differences among societal level institutions, research in the world polity tradition illuminates how modernity itself is reshaping all sectors of society, from education to firms, and at all levels, from nation-states to individuals. This perspective is historically linked to John Meyer and his many collaborators at Stanford University. These scholars study the global arena and cross-national social changes in the period since World War II, and have been particularly prolific in the areas of management, education, science, international nongovernmental organizations, human rights, and the environment (Drori et al., 2006a). Drawing on Max Weber, these scholars emphasize rationalization, progress, and individualism as the foundational cultural assumptions underpinning modern organizations worldwide. These universalistic cultural foundations are assumed to shape complex organizations in similar ways, regardless of the substantive field or specific location. Churches, government agencies, universities, and private firms are thought to increasingly take on similarly rationalized elements. As with Berger and Luckmann's (1967) phenomenological view, actors and organizations are highly scripted. Thus, as with the microfoundations ideas, the social psychology involved is closest to that of Goffman and Mead, stressing the constructed nature of reality and emphasizing that much behavior reflects the enactment of socially appropriate frames in a given context.

Contributions

The earliest work in this tradition came from Meyer's observation of schools in the 1970s. In schools, and comparable types of complex organizations, there is greater structural similarity than seems plausible if these entities are thought to reflect only immediate technical needs or situated power dynamics. Instead, organizations are creations of their external environment. In the world society tradition, the cultural frame of reference is increasingly at the world level, rather than bounded by a particular industry or even national context (Meyer et al., 1997). The global cultural changes that underpin the expansion and internal elaboration of

organizations are characterized by increasing education (especially higher education), the empowerment of individuals through emphases on human rights, and the proliferation of scientific (and social scientific) thought and method (see, for example, the collection of writings in Krueken and Drori, 2009).

This intellectual tradition is one of the central sources of cross-national organizational research. For example, in a study of national governance practices, Drori et al. (2006b) find that increasingly rationalized administration is driven by linkages to world society (measured through trade openness, memberships in international organizations, and the penetration of science), net of measures of modernization. More recently, Schofer and Longhofer (2011) have documented how world society promotes the rapid emergence of nongovernmental organizations in countries worldwide. Thus, world society influences both the nature of organizational structures (highly rationalized) and the numbers of organizations found worldwide (increasing), over and above any local technical demands.

Challenges

Given that a central tenet of world polity research is that 'actors' and 'interests' are constituted by the wider institutional environment, it is no surprise that the strongest critiques revolve around the oversocialization of actors and a lack of attention to coercive power. To a certain degree, both the logics perspective and emphases on microfoundations emerged in reaction to phenomenological neoinstitutionalism. The ideas of institutional entrepreneurs and logics emphasize individuals pursuing interests within a social framework that is largely exogenous to their existence. In contrast, the world society view supposes that the larger framework is what gives entities their status as an actor and specifies the interests that are available to them. Further, a great deal of empirical work in this tradition documents the diffusion of all sorts of formal structures (e.g., policies, plans, or laws). In turn, such a focus generates two sorts of concerns. First, some contend that formal structures are superficial (relative to actual practices), and thus the research tackles a peripheral issue. Second, others interpret the emphasis on diffusion and homogeneity as having a teleological flavor; modernity and rationalization appear to be on an inevitably increasing trajectory toward an end where all entities look superficially similar.

Conclusion

We conclude with several intentionally provocative statements in the hope they might prompt theoretical progress and new research directions. First, existing conceptions of both embedded agency and structural constraints are rather simplistic. In lieu of descriptive accounts, future work might address: Under which conditions are organizations and their members likely to have autonomy from their environment, and when are they more constrained? How can we explain the variable nature of constraints and capacities of particular actors in different contexts? For example, in more centralized political or economic settings, there may be less room for robust action by the average individual or organization. Similarly, in settings where traditional forms of authority are strongest (e.g., religion, family), there may be less room for autonomy. Institutional environments with decentralized or fragmented sources of social authority may offer greater opportunity for microlevel strategic action. In short, more carefully specified, comparative conceptualizations of the relationship between institutions and actors would be valuable.

Second, the term 'institution' needs to be concretely specified, or else its purchase becomes weak. Hand-in-hand with the growth of the neoinstitutional family has come increasing diversity and vagueness in the use of this term. If the many implicit understandings of institutions found in the literature were made explicit, then clearer distinctions between the various strains of research would come into focus and more productive boundary-spanning discussions could ensue.

Presently, the institutional paradigm is quite highly developed. With such a rich and widely used research tradition, insularity is always a risk. Rather than solely conversing with each other, neoinstitutionalists should look to insights that can be gained from other approaches. Recent studies at the intersection of social movement theory and neoinstitutionalism are one such step. Efforts to link institutional research with European traditions, such as actor–network theory, are another. A capacious theoretical pluralism will help organizational research to remain firmly rooted in addressing key puzzles in the empirical world.

New Managerialism and New Public Sector Management

Tony Cutler, Centre for Research on Socio-Cultural Change, University of Manchester, Manchester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article seeks to introduce the reader to 'new managerialism' (NM). It outlines the basic concepts and ideas underlying NM and considers the effects these have had in changing the way in which public sector services are organized. It also examines some of the principal criticisms of NM as a reform program designed to improve the performance and accountability of the public sector.

Introduction

In July 2006, the then United Kingdom Prime Minister, Tony Blair, told an interviewer from the (London) *Financial Times* that his administration was undertaking 'capability reviews' of central government departments. These reviews were designed to focus the government on 'delivery, project management and performance management' (Timmins, 2006). This statement reflected Blair's commitment to what has been termed the 'new public management' or 'new managerialism' (NM). This article is divided into four sections. The first considers the key concepts that define NM; the second examines the impact of such concepts on the organization of public sector services, particularly 'social' services such as education, health, and social care; the third section discusses the principal criticisms leveled at NM; and the concluding section seeks to bring the different strands of the argument together.

NM: Key Concepts

To approach the key concepts of NM, Hood's classic (1991) article provides a valuable starting point. Adapting his argument, three central strands of NM can be identified: the emphasis on improving the 'performance' of public sector services; the increased use of competition in the public sector; and related changes in the approach to 'managing' public sector organizations.

The emphasis on improving 'performance' involves collecting and publishing data on organizations providing public services such as hospitals, schools, and social services departments. Hood's (1991) concept also encompasses the use of incentives and sanctions (note Blair's reference to performance 'management'). The increased use of competition can take a variety of forms but a common feature is to render the provision of public services 'contestable.' The existing service provider is required to compete against alternative providers to retain the right to continue to provide the service (Hood, 1991). Finally, there are a set of changes in the approach to the management of the public sector. The public sector is 'disaggregated' (Hood, 1991) so that organizations responsible for 'strategic' decisions (not only policy making but also how performance will be measured and managed) are separated from organizations responsible for service delivery or implementing policy (see Duncan and Chapman, 2010 for this distinction in New Zealand, seen as the earliest example of a radical NM program). The management of organizations delivering services or implementing policy are to be set 'free' in that they are given increasing discretion over how performance objectives are to be achieved (Hood, 1991).

These changes are broadly justified with reference to two related objectives. The first is to focus on achieving 'results' in government (note Blair's reference to 'delivery'). The second is to create mechanisms that enhance 'accountability' for performance (Hood, 1991). Thus, NM can be presented as a coherent means of linking improved results and greater accountability. The emphasis on performance data is designed to make it clear whether the desired 'results' are being achieved and incentives and sanctions are means of 'managing' performance (Hood, 1991). Increased competition adds further pressure to 'perform' since incumbent service providers are threatened with losing their right to deliver the service. Performance data can also be used to assess how far a new provider is meeting the objectives set. Disaggregation is designed to make it easier to assess whether provider units are delivering 'results.' They are treated as 'stand-alone' organizations because the logic of disaggregation is that service managers are substantially 'free' of controls on how performance is achieved (Hood, 1991). Organizations designed to make strategic decisions are also seen as freed from having to consider detailed operational matters, which have now been 'devolved' downward.

Accountability for results is seen as having a plurality of dimensions but these dimensions are treated as complementary. The increased availability of performance data on service delivery provides 'upward' accountability to senior politicians and officials, occupying a 'strategic' role in the context of 'disaggregation' (Greener, 2009). However, such information (through the publication of performance data) is designed to increase accountability 'downward' to service users or 'consumers.' Increasing 'contestability' can also be seen as enhancing both 'upward' and 'downward' accountability. Alternatives to existing service providers can be used by senior politicians and officials to 'turn around' providers seen as consistently 'failing' to meet performance objectives (Cutler, 2007). Some forms of public sector markets, such as the use of individual budgets in social care, allow service users/consumers a role in purchasing services (Wilberforce et al., 2012). In other cases, service users are given a choice of service providers (see Considine et al., 2011 for the application of this principle in the Australian employment assistance

service). These practices can be seen as increasing accountability to users/consumers. Such a complementary view of forms of accountability conveys the impression that NM generates a 'win-win' situation where all forms of accountability for public sector service performance are improved.

The next section discusses the impact of key NM concepts on the organization of public sector services. However, before going on to address this question, three further issues are considered: the international scope of NM, the variant forms in which NM can appear, and the appropriateness of applying the adjective 'new' to NM.

NM has been embraced across a number of national jurisdictions but support for such programs has not been universal in the developed capitalist world. The principal comparative study by Pollitt and Bouckaert (2011) identified a group of 'leading' countries, Australia, New Zealand, the United Kingdom, and the United States, where support for NM-based concepts and practices were highly developed. It should also be noted with the respect to the United Kingdom that legislation on devolution of powers has meant that devolved governments in Scotland and Wales have considerable discretion over the organization of public sector social services and that this has resulted in NM organizational practices being much weaker in these devolved jurisdictions (Hood, 2007). In contrast to the 'leading' jurisdictions, NM has been much less significant in the major continental European economies such as France and Germany (Pollitt and Bouckaert, 2011 identify other countries where parts of the NM program have been adopted and others rejected). In the discussion in the second and third sections, these 'leading' NM countries will be used to give examples both of the application of NM concepts and the problems engendered by such applications.

As NM is composed of a set of elements, it is possible to find either variants in different 'leading' NM countries (Pollitt and Bouckaert, 2011) or changes in the emphasis on different aspects with changes of government, even though there is broad continuity in the adherence to NM concepts and practices (see, Duncan and Chapman, 2010 for such changes in the context of different administrations in New Zealand). An example is the extent and character of competition in public sector services. At one extreme, the role of the state can be limited to financing services and overseeing provider performance. In these, state service provision is ended and providers are drawn from the commercial ('for profit') or voluntary ('third') sectors. Such radical ventures into 'outsourcing' can also include commissioning roles for such case or care management as well as service provision for at-risk groups like children in the US state Kansas (Johnston and Romzek, 2008). In contrast, where competition is used in a 'mixed economy,' state provision is retained and incumbents are expected to compete against other public sector providers, for profit and/or third sector providers. Changes in the extent of public sector competition have varied with party control of central government. In Australia, both the Labor administration of Paul Keating and the Liberal–National administrations of John Howard exhibited a broad adherence to NM precepts. However, under Keating, the Australian employment assistance service operated with public, for profit and third sector providers, whereas Howard's administrations ended public provision in this area (Considine et al., 2011).

The general consensus in the academic literature is that NM emerged as a major public sector reform during the early 1980s (Cutler, 2007). The use of the adjective 'new' when referring to NM can broadly be treated in two ways. One is that NM is distinguished from earlier approaches to managing public sector services by the extent to which it has either invented or applied a 'new' set of techniques. This view is difficult to sustain. The logic of this position is that in the 'pre-NM' era techniques of performance measurement and management (like performance-related pay) were largely unknown in the public sector. However, there was a major performance-related pay scheme operating in elementary education in England and Scotland in the later half of the nineteenth century. This scheme linked student performance with the school budget and hence with teachers' pay (see Cutler, 2007 who gives other significant pre-NM cases of performance management in the public sector). Equally, as in the use of performance management techniques under NM, similar schemes were 'exported' to various Australian states. Arguably, the genuine claim for NM to be considered 'new' rests on the way the techniques have been applied as a set of 'doctrinal components' (Hood, 1991) across a range of services.

Thus, NM deploys a set of techniques designed to both improve the performance of public services and render providers of public services more 'accountable.' It is not a universal phenomenon. There are 'leading' countries where various forms of the broad program have been adopted, but in other major capitalist economies, its impact has been minimal. It is 'new' in the sense that, particularly in the 'leading' countries, a systematic attempt has been made to apply NM concepts across a broad range of public sector services, but individual techniques recommended by advocates of NM have a long history predating the past three decades when NM emerged as a major public sector reform program. In the next section, the argument turns to the impact of NM concepts on the organization of public sector services.

NM and the Organization of Public Sector Social Services

Measuring and Managing Performance

The emphasis in NM on measuring performance suggests that 'managing by numbers' in public sector organizations is highly desirable. 'Managing by numbers' can be classified under three principal headings: the use of 'targets'; the creation of 'ranking systems'; and 'intelligence systems' (Hood, 2007).

Targets are designed to measure performance against "one or more specified aspirational standards" (Hood, 2007: 95). An area in which targets have been frequently used is that of waiting lists and waiting times. In a number of public services, service users may be put on a 'waiting list' and the time they are waiting recorded. Instances include those waiting for an assessment by a social service department to see if they can receive a set of services, patients waiting for 'elective' (nonemergency) treatment in a hospital or waiting in a hospital accident and emergency department. The 'aspirational standard' could be to cut numbers on a waiting list to a given level or to set a maximum waiting time within which service users (or potential service users) should be assessed or receive a service. Instances of such practices include maximum

waiting time targets for elective hospital treatment, which were introduced in the English National Health Service (NHS) (see Bevan and Hood, 2006; Scotland and Wales did not have comparable targets); and times by which children at risk in Kansas would be expected to have permanent placements (Johnston and Romzek, 2008).

The logic of disaggregation means that the performance of organizations providing services can be assessed against such targets and where the target is not attained (e.g., maximum waiting times are exceeded) sanctions can be applied (Bevan and Hood, 2006). In the English NHS, for example, disaggregation has led to the creation of organizational units known as 'Trusts,' which are distinct accounting entities with accounts modeled on the form of the corporate sector and whose performance is measured. Some of these Trusts have what is termed 'Foundation' status, which means that they have more operational freedoms. Such freedoms are, however, conditional and 'Foundation Trusts' are currently regulated by a government appointed body called 'Monitor.' Like other Trusts, the performance against targets of 'Foundation Trusts' are monitored and where performance is seen as unsatisfactory one of the sanctions that Monitor can deploy is to demand an action plan from the relevant Trust management designed to correct the identified performance failure, which must be approved by Monitor.

'Ranking' systems are designed to measure the performance of 'comparable service units against one another' (Hood, 2007: 95) using a set of performance indicators. As the term suggests, performance data can be arranged in provider 'league tables' either constructed by a government agency or adapted from published government data. In the latter case, such league tables may be published in the media or incorporated in guides to the putative 'best' schools or universities among others. Publication is seen as a means to 'incentivize' improved performance, and (see below) published comparative performance data can also play a role in the extension of competition in the public sector.

The third principal form of 'managing by numbers' is 'intelligence systems.' However, in this form, the relevant 'numbers' are seen as providing 'background information,' which is subject to 'no fixed interpretation.' Such intelligence systems have a long history because the publication of data on numbers in public residential homes, patients treated in hospitals, or students attending schools or passing examinations have long been a staple feature of reports of government departments. While this approach is not absent in NM, it has played a relatively secondary role because intelligence systems provide no direct evidence as to whether 'results' are being delivered. In contrast both targets and ranking systems are designed to have a 'fixed interpretation.' Meeting the target or exceeding it (making assessments or treating patients well inside the target) is interpreted as 'success'; not meeting it, as 'failure.' The organization further up the rank order is regarded as more successful than the organization lower down and an organization consistently at the top of a rank order can be treated as a 'benchmark' for other organizations.

Increasing Competition in the Public Sector

The extension of competition in the public sector can take a variety of specific organizational forms. Insofar as such markets remain wholly or largely state financed, they have distinctive features from private sector markets (though it should be noted that where services such as railways are 'privatized' substantial public subsidies frequently operate). The 'market' aspect derives particularly from the separation of purchaser and provider roles (Duncan and Chapman, 2010). There are a number of variant forms of such markets. Various mixes of providers can operate in public sector markets. Purchasing structures can also vary considerably. Purchasing/commissioning can be devolved to professionals (case managers in social care, general practitioners in medicine). Education markets in contrast frequently operate by funding schools on age-weighted student numbers (Greener, 2009). The age weighting is designed to reflect the cost differences in providing education to students of different ages. In such a market, parents have a form of purchasing role, although supply constraints are likely to mean that while they can register a 'preference' for a given school, that school may be oversubscribed (Greener, 2009). In social care, there has been an increasing trend to 'individual budgets' where the service user is allocated a budget and becomes a direct purchaser of services (Wilberforce et al., 2012). Purchasing can thus vary from 'proxy' purchasing where the service is purchased on behalf of the service user to more direct roles in purchasing by service users.

Increased competition and performance management and measurement can operate in both complementary and competing ways. They are designed to be complementary insofar as performance data informs purchasing. Providers with a successful performance profile (shorter waiting times, 'better' examination results) could expect more 'business,' and vice versa. However, they can be competing in the sense that improved performance can be pursued either via performance management or through competition. Where the emphasis is on performance management, a key mechanism is for a central government department or a regulatory body to intervene where the performance of the provider unit is perceived as substandard. Where the emphasis is on competition, the stress is more on the pressure exerted on the provider unit by the actual or potential loss of revenue through desertion by purchasers. Even, however, where there is a preference for market mechanisms, this is not unproblematic since the obligation on government to provide locally accessible education, health, and social services can mean that allowing a public organization to 'exit' the market is limited (Greener, 2009).

Approaches to 'Managing' in the Public Sector under NM

The changing approach to 'managing' in the public sector has also led to an important set of structural changes. Disaggregation has led to the creation of new organizations. The most graphic example of this development has been the pattern of 'civil service reform' leading to creation of 'agencies' that are distinct from 'strategic' central government departments and have their own accounts and performance management regime (Duncan and Chapman, 2010). However, disaggregation does not necessarily involve the literal creation of new organizations. In education markets, for example, a given school might retain its name and be situated in the same place. Funding by age-weighted student numbers would, however, transform the

financial basis of the school by making the ability to attract students central to determining the budget. Where performance testing plays a salient role, the school may be judged on student performance in national or local examinations and tests. In both respects, the school can be seen as transformed into a quasi 'business' unit.

The logic of disaggregation has the important effect that provider units are subject to a performance management regime. The strategic/operational division means that schools, hospitals, and social services departments are to deliver services in line with performance objectives and their role in determining what these objectives will be is at best very limited (see Considine et al., 2011 for a discussion of some of the effects of such 'top-down' performance management).

Thus, NM concepts have important implications for the organization of public sector services. Provider units are usually subject to performance management regimes, which are designed to give incentives for 'good' and sanction 'poor' performance. Increased competition can take a variety of forms, some of which may result in reducing service provision by the public sector to a minimum. Disaggregation has led to the attempt to distinguish public sector organizations that play a strategic role from those that play a delivery role. The next section considers some of the principal criticisms leveled at NM.

The Critique of NM

Performance Measurement and Management

The principal criticisms of the NM approach to performance measurement and management can be broadly classified under three headings: the problem of 'proxy' measures, problems related to the attribution of responsibility for performance to particular organizational units, and the problem of 'gaming.'

The problem posed by 'proxy' measures arises because they may fail to reflect the objectives of a service. One broad objective of education, for example, could be the development of a capacity for critical thinking. However, educational performance measures usually focus on examination and test results. It is possible, however, to 'teach to the test,' i.e., coach students so they do well in particular tests and/or examinations. Such 'rote learning' can be contrary to a conception of critical thinking in which the student is able to transfer independent analytic skills to a number of contexts (for a discussion of both contemporary and 'pre-NM' examples of this problem, see Cutler, 2007).

Problems of allocating responsibility for performance come in a variety of forms. The notion that organizations designed to deal with service delivery/policy implementation can be regarded as 'stand-alone' bodies responsible for their performance is difficult to reconcile with interorganizational relationships in the public sector. An interesting example of the problems for performance management generated by such interactions is provided by Johnston and Romzek's (2008) study of services for children at risk in Kansas. Service providers are subject to a performance target for the time taken to place children whose cases they are managing. However, such placements are subject to the approval of a judge meaning that the service provider cannot control whether or not they achieve the target.

A different type of attribution problem arises with respect to ranking systems. These are often based on a composite set of indicators covering a wide range of services. Such rankings are subject, inter alia, to 'categorization' errors where "perplexity about how to fit cases into categories may result in faulty assignment of these cases" (Hood, 2007: 100). The nature of such errors can be understood if the mechanisms of such ranking systems are examined. A first stage in the process is the transformation of data on performance into a score for a given service. This in itself is a complex process because it is likely to require a large number of quantitative indicators (to reflect multiple dimensions of the services) and qualitative material such as inspection reports. A second stage is the generation of an organizational score that frequently will involve a service weighting. Such a weighting could be justified on the grounds of the relative importance of services (e.g., local government might regard social care as more important than leisure services) and/or on grounds of the relative expenditure on the services. Finally, the organization scores themselves can be classified into categories, e.g., a score in a certain range is 'poor,' another 'fair,' and another 'excellent.' The overall categorization might trigger actions like central government regarding a 'poor' local authority as requiring management changes.

Categorization error can occur at all stages. The first may involve implicit weightings of particular indicators and reports, but these may be difficult to justify. At the second stage, the principle of weighting might appear reasonable but specific weightings more difficult to justify; for example, should social care rate be twice as important as leisure services or three times? Finally, in terms of overall points scores, 30 points may be classed as 'fair' and 29 as 'poor' but there is no obvious justification for this, and in any case, these overall scores are themselves subject to categorization error.

The final key problem is posed by 'gaming.' As has been stressed, it is a characteristic of performance measurement and management under NM that there are powerful incentives and sanctions (Pollitt and Bouckaert, 2011). This engenders corresponding incentives to 'game' the system, i.e., adopt practices that can be seen as at variance with overall service objectives, while they enable the requisite performance objective to be met. A classic example of gaming occurs in educational performance measures that use a threshold. Such a performance measure would be the percentage of students achieving test or examination results within a particular range (e.g., grades A–C) (see Cutler, 2007 for an example from UK education performance indicators). A 'gaming' approach to such a threshold is for a school to concentrate resources on the group who are currently not expected to achieve the threshold but who, with sufficient additional help (e.g., extra tuition), might be expected to do so (the 'current Ds' but 'potential Cs'). This approach is designed to maximize the school's score on the relevant indicator within the resource constraints within which the school operates. The concentration of resources in this way means that two other groups are treated inequitably: those who are regarded as certain or highly likely to fall within the threshold because they do not need any additional help to get them over the threshold and those who are regarded as having virtually no chance of reaching the threshold. Arguably, this approach to maximizing the performance indicator score contradicts an implicit objective of the service, namely, to

provide, as far as possible, an appropriate education for individual pupils. The potential Cs are being favored not because they have any greater claim to educational resources but because favoring them is perceived as conducive to improving performance on the indicator (see Booher-Jennings, 2005 for such practices in the Texas education system).

Greater Competition

The principal problems with increasing the scope of competition in the public sector to be discussed in this subsection are the problems posed by managing public services through contracts, the impact of competition on individual service units and on overall service performance, and the impact of different conceptions of the service user/consumer of public services.

Insofar as maximum use is made of competition, this requires extending the range of providers used outside an internal market to encompass for profit and third sector organizations. However, this also requires drawing up contracts specifying not only expected costs of provision but also expected service 'outputs' and penalties for failure to achieve such outputs. The difficulty of doing this varies with the nature of the service provided. Where the service is relatively standardized (e.g., elective operations like hip replacements), such contractual terms may be relatively easy to specify. However, where services are more complex and expected outcomes less determinate (e.g., treatment for cancer), contracts are necessarily more problematic (Greener, 2009).

A related problem concerns the assumptions behind contracts in the context of contestability. If operations like hip replacements are treated as a 'quasi industrial' form of health care then it might be assumed that patients are relatively unconcerned regarding continuity of contract with the provider. The operation may be undertaken on a day surgery basis and continuity of subsequent care may be provided by a general practitioner not the surgical provider. However, in many instances of social care, such assumptions do not hold. Johnston and Romzek's (2008) study of services for at-risk children in Kansas found evidence that change or threat of a change in contract provider and case manager generated considerable unease in both children and their families. A state official (in a state that has completely outsourced this service) was quoted as saying that such contractual transitions were 'very tough on kids' and 'tough on families.'

An important example of the view that NM markets generate complementary benefits is the assumption that public sector markets extend 'choice' and that the exercise of choice drives up standards of service provision. Thus, Tony Blair argued that "choice puts the levers in the hands of parents and patients so that they as citizens and consumers can be a driving force for improvement in their public services" (cited in Clarke, 2006). What is assumed here is that there is a parallel gain at the individual and collective levels. However, it is incorrect to assume such a facile connection. An important illustration of attempts to link increased competition in the public sector with improvements in overall performance standards is the creation of new 'subsystems of schooling' (Morris, 2012), which compete for students with other schools in a national public school system. Examples of such subsystems are Charter Schools in the United States and 'free' schools in Sweden, which have been imported into English education by the current UK coalition government. The argument advanced by proponents of such increased competition is that it will improve both individual choice and overall school standards. However, such a view has been repudiated by the Organisation for Economic Cooperation and Development (OECD) (though the proxy problem should be noted here as the OECD discusses education standards predominantly in the context of test/examination data). The OECD concluded that while higher performance levels could be seen in many cases in these school subsystems, this was often accounted for by 'the higher socio-economic status' of students in such schools (cited in Morris, 2012: 102). The OECD went on to argue that 'cross-country analysis' suggested that school "systems as a whole do not benefit from higher rates of school competition" (cited in Morris, 2012: 102).

A final problem for public sector markets relates to the implications of changing and contradictory conceptions of the service user. In the passage quoted above, Tony Blair used the term 'consumer' but some supporters of public sector markets have wanted to replace public sector 'consumerism' with what they term 'personalization.' From a 'personalization' standpoint, the emphasis on offering 'choice' is too limited because it is choice between a 'menu' set by the service providers. Thus, a difficulty that can arise with choice is that it is between service providers who offer broadly the same service, so schools are often effectively competing to offer better measured academic performance, or hospitals, shorter waiting times (Cutler et al., 2007; see Considine et al., 2011 for increasing homogeneity of services in the Australian employment assistance service). In contrast, personalization requires 'coproduction' where the service user participates in the design of the service. There are clearly tensions between such a conception and the top-down approaches to performance management (Cutler et al., 2007). One of the conditions regarded as crucial by NM advocates of public sector markets is a plurality of providers as a condition of effective competition. However, there are potential tensions between personalization and the aim of having a plurality of potential service providers. For example, devolving budgets to individual users could throw up problems of providers having insufficient business to make them viable, having to incur higher service provision costs in the context of 'austerity'-driven reduced budgets, and having to bear higher transaction costs (Wilberforce et al., 2012).

The final set of critical issues regarding NM relates to the premises underlying the structural reorganization of public services driven by NM concepts. Here the distinction, underlying disaggregation of the public sector between organizations playing a strategic and those playing an operational/delivery role, will be considered. Disaggregation of the public sector was based on distinguishing strategic organizations like central government departments, which were responsible for setting policy and measuring the extent to which policy objectives were realized, and organizations concerned with the delivery of services and policy objectives. However, this presupposes that it is possible to distinguish clearly the effects of strategic and delivery-related decisions.

A major criticism of this view is that it is often unclear whether problems with the achievement of policy objectives were the responsibility of departments dealing with strategic

decisions or those charged with delivery/implementation. An instance of the problems of allocating responsibility in such a disaggregated structure is the issue of gaming. Gaming can be manifested in the form of shifting organizational resources from areas of organizational activity that are unmeasured or where a particular activity is not relevant to high-profile targets (for health, see Bevan and Hood, 2006). This, like the gaming education thresholds discussed above, can be regarded as generating inequitable practices. Users of, from a performance management point of view, low-profile health services or students regarded as either certain to get into the threshold range or having no chance of doing so suffer relative to service users who are 'relevant' to high-profile performance objectives (see Considine et al., 2011 for parallel practices in the Australian employment assistance service). In this sense, gaming represents a policy failure.

However, if this is a policy failure, it should be possible, in a disaggregated public sector organizational structure, to locate responsibility for this failure clearly. One immediate suggestion is that the 'fault' lies with the service delivery/policy implementation organizations. They are gaming the target/indicator and as a consequence responsible for the corresponding inequitable practices. Yet, a plausible case can be made that the organization responsible for strategy is at fault. The strategic organization was responsible for 'sending the message' that certain targets/indicators were much more significant. Equally, if such targets/indicators have the potential for gaming, why was this not controlled by the strategic organization (possible methods are discussed by Bevan and Hood, 2006). What is important here is that either account cannot be rejected unproblematically and that disaggregation does not locate responsibility for policy failures.

Conclusion

NM is based on a set of 'doctrinal components' (Hood, 1991) that have been applied to radically change the way in which government is organized. The effects of NM are diverse. It has greatly increased the measurement of the 'performance' of public sector organizations and spawned the application of incentives and sanctions to 'manage' performance. It has also encouraged much more extensive use of competition in the public sector. It has set in train a process of 'disaggregation' whereby organizations seen as specializing in 'strategic' decision making are separated from those involved in 'delivery' or policy implementation.

NM has operated on a contested terrain. Its advocates see it as a means of radically improving the performance of public sector organizations and bringing them into line with the demands of a more 'consumerist' society. The critics of NM perceive major problems in it. They argue that performance measurement and management has led to the use of crude performance measures and encouraged 'gaming,' which can compromise service standards. Increased competition in the public sector has been in tension with the desire of many service users for continuity of provision. Personalization, particularly in a putative 'age of austerity,' has been difficult to reconcile with encouraging a plurality of providers. Disaggregation, for critics of NM, is seen as offering a false hope of clear lines of accountability for policy success and failure. NM promised and promises a new era of a better managed public sector but 'delivering' on these pledges has proved problematic.

New Media and Democracy in the Arab World

David M Faris, Roosevelt University, Chicago, IL, USA

Abstract

New media have had a particularly sharp impact on the Middle East, where states at the turn of the century remained dominated by authoritarian regimes and information monopolies. New media were used in the 2000s to circumvent censorship, to build communities of dissent and identity building, and to contribute in causally distinct ways to the wave of uprisings known as the Arab Spring. However, robust structures of authoritarian rule remain prevalent in the region, and regimes are increasingly savvy in leveraging new media tools to their own advantage.

What has been the impact of new media on political authoritarianism in the Middle East? Have emergent digital technologies overturned media hierarchies, challenged authoritarian rule, and transformed patterns of social mobilization in the region? Or have new media, as other scholars argue had little effect on entrenched patterns of authoritarian rule? The effort to theorize and analyze the impact of digital media on the Middle East has created a lively and sometimes contentious debate between scholars who study the region. New media in the Middle East have generated such sustained attention that there are now multiple academic journals devoted solely to regional mass media. In addition, articles about the impact of new media in the Middle East have appeared in dozens of communications, sociology, anthropology, and political science journals, as well as have been the focus of both single-author and edited volumes. This long-term scholarly effort has resulted in distinctive subfield whose signature feature is that it cuts across multiple disciplines, whose practitioners often do not read or cite one another's work.

First, a caveat: There is no longer anything 'new' about satellite television. Al-Jazeera is nearly 20 years old and the recipient of sustained scholarly attention that almost constitutes its own separate academic literature. Most major satellite broadcasters, including Al-Arabiya, the Lebanese Broadcasting Corporation and MBC, have been operating since the 1990s. This is not to suggest that satellite television is not an important subject of inquiry, but rather that patterns of consumption and use of television are so markedly different from those of the Internet and mobile phones as to necessitate a separate inquiry. It may not be long before digital media are also not 'new media' but for the time being the Internet and mobile phones can still be referred to as part of this general construct. This article will, therefore, confine itself to reviewing studies on the affects of the Internet and wireless telephony on society and politics in the Middle East. As these technologies 'took off' in the early 2000s for most societies of the region, the focus of this article will be on the period between 2000 and 2013. For the remainder of this article, new media can be assumed to refer both to the Internet, as well as to the mobile telephony platforms that are increasingly used to access the Internet.

In 2000, Jonathan Alterman argued that 'new media' might be received or used quite differently in the Middle East, suggesting that the Internet was unlikely to transform media consumption patterns in the region in the same way that they had done in other regions. He cautioned that "we need to think about the possibility that the Internet, which has transformed so many transactions and communications in North America and Western Europe, will not have as dynamic an effect on the Arab world" (Alterman, 2000: p. 356). The critique that new media's impact or growth curve in the Middle East would be markedly different from its development in the West has not been borne out by the unfolding of history since Alterman's article was published. If anything, the growth of Internet penetration in the region has been even more explosive than it was in the United States and Western Europe in the 1990s, and the region's citizens have used the new medium in more or less precisely the same way that it has been employed elsewhere. One can contest the relative importance of new media diffusion vis-à-vis other social and political variables in the region, but it would be difficult to argue that their impact has not been dynamic. This article focuses on a small number of new media impacts in the Middle East: first, on the practice of authoritarianism, second, on collective action, and third, on identity. The study is limited in nature, since the literature on new media in the Middle East has become expansive enough to defy even a lengthy cross-field summary.

New Media and Regional Authoritarianism

The academic literature on the Middle East is replete with unjustified exceptionalism. But one area where the Middle East was incontrovertibly different from other regions at the beginning of the new millennium was in the area of political rights and representation. At the turn of the new millennium, the Middle East was one of the last global bastions of entrenched authoritarian rule (Bellin, 2004), where there was one consolidated democracy (Israel excluding the Occupied Territories), one transitional democracy (Turkey), and a host of states that varied from hybrid regimes (Lebanon) to fully closed and brutal autocracies (Syria, Libya, and Iraq). Most of these regimes also exercised substantial or complete control over local media environments, to the extent that in many regional states, the constrained critiques emanating from Al-Jazeera represented the most radical dissent that most ordinary citizens had access to. In this constrained environment, the diffusion of self-publishing technologies like Blogger, as well as access to the largely unfettered (at least at first) global

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95085-2

Internet, was genuinely disruptive in ways that helped lead to the Arab uprisings of 2010–11. Self-publishing technologies allowed individuals across the region the ability to create their own platforms of self-expression in the form of blogs and web sites, and gave others with Internet access the ability to access this new information and to engage in spirited debate about ideas. While satellite TV similarly crossed boundaries and carried unprecedented criticism of regime practices in the late 1990s and early 2000s (Lynch, 2006; Sakr, 2002), it was a medium that lacked the Internet's critical many-to-many communication properties.

At least in the early days of the Internet, authoritarian regimes in the region were generally incapable of censoring or filtering the Internet, and thus for a brief period of time in places like Tunisia, and for longer periods of time in countries like Egypt, the Internet was providing a site of free-wheeling discussion, dissent, and sharing, even if only for the few citizens with access to the Internet in the early 2000s. It was not long before citizens using these self-publishing platforms began to make organized calls for reforms in state public policy, particularly in the blogging hubs of Egypt and Bahrain (Al-Malaky, 2007). Unlike the stodgy state media outlets of the tolerated print media universe, the Internet tended to disproportionately feature the edgy voices of younger citizens, who felt left out of the power structure and who argued that the Internet gave "voice to the voiceless" (Faris, 2013: p. 119). Together these activists were able to create a set of "frames," or "conceptual tools for both media creators and audiences to convey, interpret, and evaluate information" (Mosemghvdlishvili and Jansz, 2012: p. 484). Finally, like many media commentators locally and in the West, authoritarian regimes for a time failed to take the threat of digital activism seriously. Together these factors led to several causal paths for the use of digital media and political change in the region. First, digital media platforms reduced communication and coordination costs for political actors operating under conditions of repression and information scarcity (Shirky, 2008). Second, early adopters of new media platforms and applications in certain regional states formed small, loosely-linked networks of dissent that proved critical in advancing long-term critiques of regime policies whose effects were difficult to see at the time (Faris, 2013: pp. 49–84), especially in Egypt and Bahrain (Schleusener, 2007). Crucially, new media offer the opportunity to publish opinion and join conversations on blogs or social media like Facebook and Twitter to any literate person with an Internet connection, leading to what Manuel Castells has termed 'the rise of mass self-communication' (Castells, 2007). Third, the Internet provided a forum for women, minorities, and other marginalized publics to shape their identity and participate in alternative public spheres (Wheeler, 2006). Fourth, new media made it easier for individuals in authoritarian societies to reveal their true feelings about authoritarian rule, and to avoid the public 'preference falsification' that deprives individuals of knowledge about the intentions and beliefs of those around them (Kuran, 1991). The default public nature of new media led to the creation of sometimes unintentional 'communality' (Bimber et al., 2005) and facilitated processes of 'frame-alignment' and in some cases, of 'informational cascades' – sudden, widespread changes in popular beliefs and preferences about public issues (Lustick and Miodownik, 2005; Bikchandani et al., 1992). Finally, new media 'allow communication to take place across borders, and forms of international solidarity to spring up relatively quickly' (Aday et al., 2010: p. 24). Collectively, these factors had the effect of posing new and unexpected challenges to authoritarian rule in the Middle East during the 2000–13 period, including undermining state media sovereignty and control (Lamer, 2012) culminating in the 2010–11 Arab Spring but followed by a period of political retrenchment and turmoil that highlighted the limitations of new media as an agent of social change.

New Media and Identity

The affordances of new digital technologies were not just seized upon by the secular activists who received so much press in the West. Scholars working on new media in the Middle East have largely assumed from the beginning that they would be particularly useful for transnational identity-building and linkage. Eickelman and Anderson argued in 1999 that "a proliferation of media and means of communication multiplied the possibilities for creating communities and networks among them, dissolving prior barriers of space and distance and opening new grounds for interaction and mutual recognition" (p. 3). Like satellite TV, the Internet by its very nature effortlessly crosses political boundaries and links "diffuse individuals with common interests" who may lack any other way to coordinate their actions (Shirky, 2008). In the Middle East, there are several plausible beneficiaries of digital media's transnational scope and reach. First, the Internet affords diaspora communities the opportunity to influence, and to be influenced by, political and social trends in home communities, perhaps deepening democratic engagement for citizens who would otherwise be marginalized (Brinkerhoff, 2009). During the Egyptian uprising, for instance, diaspora Egyptians in major cities across the world, including London, New York, and Chicago, used the Internet to organize rallies in support of the revolutionaries. The Syrian exile community has been similarly active both online and off-line since the civil war began in March 2011. Perhaps no community has seen a greater impact from digital media than the stateless Kurds, spread across multiple Middle East and North African (MENA) states including Syria, Turkey, Iraq, and Iran. The Kurds are subject to perhaps the strongest centripetal forces on national identity in the whole region – unlike, for instance, even the Egyptian Copts, the Kurds do not have a national home, and have been subject to the attempts of state leaders to suppress or eradicate expressions of Kurdish nationality, especially in Turkey during the course of the twentieth century. Kurdish web sites produced in diaspora have thus become an important source of contention, and have served to reinforce national identity in exile and in the homeland, with some scholars arguing that digital media have "assumed the role of print media nowadays' in the theory of 'imagined communities" advanced by Benedict Anderson (Candan and Hunger, 2008: p. 145). The Internet may also play a role in enhancing notions of pan-Arab nationalism, or *qowmiyya* nationalism, although this potentiality has yet to be the focus of sustained social–scientific inquiry. Certainly, the Internet has proven to be

a forum of empowerment for the region's women, many of whom played critical activist roles in the Arab Spring. As Courtney Radsch has argued, "Throughout the region, women have taken to the streets in unprecedented numbers, translating digital advocacy and organization into physical mobilization and occupation of public spaces in a dialectic of online and offline activism that is particular to this era" (2012: p. 4). Even in conservative Saudi Arabia, half of all bloggers are women, evidence that the new medium offers opportunities for participation and contestation that are not available offline (Open Net Initiative 2009).

Perhaps the transnational group that has received the most attention is global Islam. In fact, from the beginning, Islamist groups across the region used the proliferation of self-publishing tools and social media applications to network with one another, spread their message, and push for political reform of authoritarian states. In Egypt, young members of the Muslim Brotherhood began publishing blogs during 2006–07, in some cases challenging the organization's official positions (Lynch, 2007). The Egyptian Brotherhood was also at the forefront of its own kind of public diplomacy, using the group's English-language Web site, *Ikhwanweb*, to challenge both Egyptian and Western perceptions of the group, to advocate for imprisoned senior Brotherhood figures, and to infiltrate and disseminate information about military trials of the group's leaders (Faris, 2013: pp. 132–143). More broadly, the growth of digital media affords nonelites the opportunity to participate in conversations about Islam and Islamic practices, and to debate *al-maslaha* (the good life) together in digital forums (Bunt, 2009). One of the effects is a kind of broadening of religious authority, where less traditionally learned men may rule on religious matters through digital interaction in what Bunt terms Cyber Islamic Environments (CIEs) (Bunt, 2009).

New Media and the Arab Spring

The role of digital media in the series of uprisings that shook the Middle East beginning in Tunisia in December 2010 has also been the subject of sustained scholarly inquiry. Observers seeking a direct causal role for digital media were probably frustrated, but social media and mobile phones played at least a supporting role in nearly every revolt. The importance of new media in the Arab Spring is evidence of the multiple ways that these technologies have become embedded in everyday life, and how they have been transformed from the technologies of a wealthy elite. It was in Egypt where the impact of new media was the clearest. The Egyptian blogging community had over time been transformed by the arrival of social media platforms like Facebook and Twitter. Beginning in about 2008, young, digital-savvy Egyptians had used the group-forming capability of Facebook to organize increasingly daring challenges to the Egyptian state, beginning with the 6 April 2008 general strike organized online by a Facebook group (Faris, 2008). What became known as the April 6th Movement was one of the major organizers of the initial 25 January 2011 demonstrations that led to the ouster of Egyptian strongman Hosni Mubarak. The April 6th pioneers were joined by a group called We Are All Khaled Said, the namesake of a murdered Alexandrian whose plight came to stand in for experiences of torture, brutality, and impunity shared by many Egyptians. Founded in June 2012, the Khaled Said group soon featured hundreds of thousands of members, and whose Facebook wall was the site of open plotting about the date and form of the initial protests. What some have called 'cyberactivists' were also crucial in organizing opposition to the rigged December 2010 parliamentary elections, around which contestation spilled over into January 2011 (Khamis and Vaughn, 2011). While there is limited data about what led Egyptians to the protests on 25 January, there is some evidence to suggest that significant numbers of Egyptians learned about the protests through Facebook and Twitter (Tufekci and Wilson, 2012).

The role of digital media was much more varied across the other Arab Spring cases. In Syria, rebels leveraged the information capabilities to, at times, outsmart the regime. As Lindsey argues, "Amateur video showed rebels across the region the location of Syrian Army Republican Guard convoys, air assets, and checkpoints" (2013). Syrians also used Facebook to coordinate the dates and times of the initial Friday protests during March–April 2011. In Tunisia, unlike in Egypt, digital activists did not spark the initial revolt, but rather exploited it through publicizing subsequent protests (Faris, 2012), and some scholars have argued that the Wikileaks scandal was particularly damaging for the Tunisian regime, as it helped expose some of the more outrageous government corruption. And in Yemen, where rates of Internet and mobile penetration were particularly low, it is difficult to locate any unique causal role for new media.

However, the aftermath of the Arab Spring has certainly provided substantial evidence for scholars skeptical that digital media can permanently transform authoritarian regimes. In Egypt, the democratic transition instigated by digital activists collapsed in 2012–13 into a military coup and a seemingly strengthened authoritarian regime. Attempts to use existing digital platforms, including 'We Are All Khaled Said,' as well as new permutations of digitally mediated activists groups, like Third Square, were unsuccessful. Despite continued increases in access to the Internet in Egypt, Tunisia, Bahrain, and Iran, activists were unable or unwilling to follow their Arab Spring organizing methods with sustained political efforts. In Syria, while digital platforms were used to coordinate and facilitate early protests during March–April 2011, and while digital media have been crucial in keeping the global community apprised of what is happening inside the country (Aman and Jayroe 2013: p. 331), digital media have clearly been eclipsed by physical events on the ground and the overwhelming violence and brutality of the combatants. Digital dissidents were also comprehensively routed in Bahrain, as well as in Iran in the chaotic period following the reelection of Mahmoud Ahmedinejad in 2009.

The difficult aftermath of the Arab Spring, and the different trajectories of uprisings in Arab states, are both supportive of the notion that digital media's impact depends seriously on the political environment in each case. Scholars have thus far had a difficult time empirically linking the spread of digital technologies with democratization. Of the studies to undertake quantitative analyses of this question, there has been substantial disagreement. Among the first was Calfano and Sahliyeh's analysis of Internet penetration and political rights, which

found that an increase in Internet access was affiliated with a decline in political rights across the region (Calfano and Sahliyeh, 2008: p. 71). It is certainly true that the region's most wealthy states, and thus the places with the highest rates of Internet penetration, were among the least likely to witness widespread social unrest in 2010–11 (Wolfsfeld et al., 2013). Wolfsfeld et al. argue that protest tends to precede digital organizing, rather than the other way around. While there were stirrings of protest in Saudi Arabia, the United Arab Emirates, and Kuwait, there certainly was nothing like the broad-based, digitally-inspired street movement in Egypt, or even the digitally-coordinated protests that emerged in Tunisia following the initial spark.

On the other hand, there were modest protests in Saudi Arabia, Kuwait, and Oman (Howard and Hussain, 2013: pp. 6–9) and regimes responded with conciliatory policies including direct financial grants to citizens (Kuwait) or promises of reform (women gaining the right to vote in Saudi Arabia). And wealthy, highly-connected Bahrain was the site of a major uprising, albeit one with sectarian overtones, that required Saudi forces and extreme brutality to be put down. Other work has found an empirical link between increased access to digital media technologies and political reform over the long term (Howard, 2010). With very few exceptions, the most vociferous critics of the link between digital media and collective action have been nonacademics whose treatment of evidence and methodology are questionable at best. The crux of skepticism revolves around the continued importance of satellite television, particularly that of Al-Jazeera (Alterman, 2011: pp. 103, 104), and of the political context of collective actions. Very few scholars would likely be willing to sign onto the notion that digital media are either necessary or sufficient for widespread protest activity; at the same time, the reality of digital diffusion, the increasing density of digital networks, and the growing embedding of digital media in the everyday practices of ordinary life mean that, for the time being, we are unlikely to witness widespread protest activities in the Middle East without a leading digital component. And because of the failure of most Arab Spring uprisings to lead to genuine democratization, digital technologies are likely to remain the default mode of organizing and expression, even where states undertake sincere and sustained efforts to disrupt networks, erect information chokepoints, and imprison activists.

Regimes Respond

States, however, have not taken these challenges lightly, and have now responded in a variety of ways to the challenge of digital dissent. Generally, the more politically repressive states, including Iran, Syria, and Saudi Arabia, were most determined and successful in designing strategies to contain digital activism. While not technically part of the Arab world, Iran has been a key regional leader in disrupting the democratizing potential of new media. In 2006, the regime went as far as slowing the available download speed for Internet users, in an attempt to prevent the spread of viral videos challenging state authority. Tunisia, on the other hand, adopted a generic regime of censorship and 'filtering,' using off-the-shelf technology to block access to political sites on the Internet. Egypt was an outlier, in that the Mubarak regime made no serious attempt to interfere with the smooth functioning of the Internet – restricting itself largely to piecemeal harassment and detention of digital activists (Boas and Kalathil, 2002; Freedom House 2011). As Freedom House noted of Egyptian authorities in 2011, "Rather than relying on technical content filtering or monitoring, they typically employ 'low-tech' methods, such as intimidation, legal harassment, detentions, and real-world surveillance of online dissidence."

And by the standards of the region, even Egyptian harassment of bloggers and activists was tame. Generally, though, even deliberate and well-funded censorship regimes were vulnerable to circumvention by committed activists, who in Tunisia were able to use proxy servers to access blocked content (Faris, 2012). The main effect of the censorship regimes employed by Iran, Tunisia, Syria, and others was to drive activists into exile, and to heighten the importance of information produced in other countries and then made available to users via circumvention software. While the idea of an Internet 'kill switch' has received a great deal of press attention, most attempts to actually shut down Internet service had been relatively brief until the Syrian civil war.

By mid-decade, most regional states had recognized the threat posed by the diffusion of the Internet to the tight control over information traditionally exercised by authoritarian regimes. In responding to these threats, regimes have access to an increasing repertoire of global censorship, filtering, harassment, and innovation pioneered by likeminded authoritarians in China and Russia (both at the forefront of authoritarian responses to digital activism). As Youmans and York note "Repressive regimes are demonstrating learning curves when it comes to limiting the usefulness of social media for activists" (Youmans and York, 2012: p. 323). Jiang termed authoritarian public spheres that nevertheless contain technological or legal limits on digital speech 'authoritarian deliberation' (2010). Iran and Saudi Arabia remain at the forefront of regional attempts to construct tight censorship regimes that can prevent ordinary citizens from accessing sensitive or politically damaging information. While the crisis surrounding the reelection of Mahmoud Ahmedinejad to the presidency in 2009 provided proof that new media, particularly Twitter, played a substantial role in mobilizing external audiences to support the country's besieged protestors (Aday et al., 2010), those activists ultimately failed. Iran famously shut down its mobile networks during the 2009 postelection crisis (Rahimi, 2013: p. 40), but the state's attempt to build a longer-term and more durable censorship regime is of greater importance, highlighted by the creation of parallel social media Web sites, such as 'Velayatmadaran' (a Facebook copycat) that the state can suitably police and censor (Rahimi, 2013: p. 41). Saudi Arabia was among the first global regimes to construct an elaborate and expensive filtering regime, licensing private operators to provide Internet service but channeling all access through the same hub (Open Net Initiative 2010). Ultimately though, even determined attempts to shutter networks during moments of crisis in Libya and Egypt failed to dissuade knowledgeable and dedicated activists from accessing proxy servers and other workarounds.

However, it was also the embattled MENA autocrats in the post–Arab Spring period who deployed, under duress, new methodologies for shutting off access to the Internet. In Egypt,

the regime shut down access to the Internet altogether shortly after the 25 January protests began (Lynch, 2012), although by all accounts this tactic backfired as it forced those who were following along online to go outside and see what was happening in the streets. In Bahrain, regime loyalists used Facebook and blogs to attack leading dissidents, and in Syria, pro-Assad groups spammed Twitter with #Syria hashtag posts and created a popular Facebook group called 'Syria Revolution 2011' that hosted regime supporters (MacKinnon 63–64). Perhaps no effort was more comprehensive than the creation of the regime-supported Syrian Electronic Army (SEA) which was designed to harass, discredit, block, or dismantle the new media efforts of the opposition.

Conclusion

New media have had a clear and substantial impact on the Middle East. By offering alternative platforms of expression and dissent, the early Internet led to the creation of distinct blogging and collaborative communities in places like Egypt, Bahrain, and Iran (Sreberny, 2009). Later developments in what came to be known as 'social media' provided activists with new coordinating, information-sharing, and group-forming tools that led to escalating challenges against regional authoritarian regimes. New media are now deeply embedded in the everyday practices of the region's citizens, and while rates of access and use still vary widely across the region, the upward trend is clear even in the poorest states. These disparate forms of media are likely to play important roles in democratizing states like Tunisia and Iraq as well as in states where authoritarianism has weathered the Arab uprisings, such as in Egypt, Bahrain, Iran, and Syria. The causal impact of new media in the Middle East has been the subject of vigorous, popular, and scholarly dispute, but what is clear is that these technologies have served as important causal variables in social and political contestation even as local contexts serve as important intervening variables that may lead to divergent political trajectories. Above all, new media are now entrenched in the Middle East, and the study of their impact will remain a topic of sustained interest to scholars, journalists, and policy makers for the foreseeable future.

New Media and Social Capital

Gustavo S Mesch, University of Haifa, Haifa, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The rapid increase in the adoption and use of information and communication technologies among the population of developed and less-developed countries has prompted researchers to investigate the social impact of these technologies on patterns of interpersonal communication; access to educational, housing, and job opportunities; and the attainment of social status. In the study of the social impact of information and communication technologies, the theory of social capital has served as an organizing framework. The purpose of this article is to expose the reader to the essential concepts and empirical findings that have guided this research. The focus of this article is on studies that have used social capital or some of its dimensions as the dependent variable of the study.

Social media have become a varied and pervasive platform for user-generated content. The use of such vehicles has implications for one's social capital, both on the individual level and on the collective level. This article reviews the early and more current literature about the relationship between the use of social media and the attainment of social capital for both the individual and the community at large. The findings also have implications for future studies in this area.

Social Media

Social media is a concept that involves the use of web and mobile-based technologies to facilitate the mass sharing of user-generated content and the maintenance of interactive communication with other users. In that sense, it is a concept that describes a wide variety of software enabling individuals, organizations, and communities to gather, communicate, create, and share multimedia content, collaborate with one another, and play together. Given its purpose, social media include six different types of tools: media for collaborative projects (e.g., Wikipedia), blogs and microblogs (e.g., Twitter), content communities (e.g., YouTube), social networking sites (e.g., Facebook), virtual game worlds (e.g., World of Warcraft), and virtual worlds (e.g., Second Life) (Kaplan and Haenlein, 2010). Social media is accessible to individuals, organizations, and communities, allowing them to easily produce and change content, and to reach large audiences in real time.

Social networks have played a critical role in the adoption and expansion of social media. Most of the applications require one to be invited to participate and/or to invite one's acquaintances, family, and friends to join and become linked to the user. Bringing along a network of acquaintances is a condition for having access to the content of others and for sharing one's own content with others. Thus, the worldwide adoption of these applications had led social media to play an important role in social and political mobilization, advertising, and brand building, and interpersonal and mass communication. The dissemination of content generated through these formats and their interactive characteristics have prompted researchers to try to understand the role of social media in the production and maintenance of social capital.

Social Capital

The idea behind social capital is that involvement and participation in groups can have positive consequences and benefits for individuals and communities. Examples of such benefits include access to information, emotional support, exposure to different ideas, and social and political deliberation, and engagement. Scholars regard social capital as being embedded in the structure of social relationships. Given that social applications on the Internet are used to access information, maintain existing ties and create new relationships, it is important to study the implications of the use of social media for the acquisition of social capital.

Social capital is complex, especially because researchers approach it from various disciplines and apply the concept to a wide variety of social phenomena. For these reasons, there are significant variations in the measurement, sources, and outcomes of the concept. The studies of Bourdieu (1986), Coleman (1990) and Putnam (1993) are the most cited sources in contemporary discussions on social capital. Bourdieu (1986) defined social capital as "the aggregate of the actual and potential resources which are linked to possession of a durable network of more or less institutionalized relationships of mutual acquaintance or recognition" (p. 248). For Coleman (1990), "social capital is defined by its function. It is not a single entity, but a variety of different entities having two characteristics in common: they all consist of some aspect of social structure, and they facilitate certain actions of individuals within the structure" (p. 302). According to Coleman, social capital can take on forms such as obligations and expectations, information potential, norms, and effective sanctions.

For Putnam (1993), social capital is a community level resource. He defines social capital as "… features of social organization such as networks, norms and social trust that facilitate certain actions of individuals who are within the structure" (p. 67). Putnam's argument is that social networks and social norms are critical for social cooperation, coordination, and collaboration. For this reason, social capital has important consequences for democracy, as civic engagement and participation are a measure and consequence of increasing or decreasing levels of social capital (Putnam, 1993).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95087-6

From this review, we may infer that the most widely used dimensions of social capital are social networks, trust, and norms of reciprocity. Social networks concern the extent of individual participation in various types of organizations, communities, and informal networks. Trust is defined as the level of confidence that people will act or are expected to act as they say they will, or that what they say is reliable. Norms of reciprocity refers to shared understandings, and informal rules and conventions about continuing relationships of exchange at any given time. These norms involve mutual expectations that assistance given now will be repaid in the future (Putnam, 1993). This view of social capital stresses on aspects of the connections people create through civic engagements, community, and online-based activities.

Linking Social Media and Social Capital

Various disciplines have undertaken the study of the association between information and communication technologies and social capital. In general, these studies have focused on the effects on the individual level or on the collective, community level.

On the individual level, early studies were concerned with the extent to which frequency of Internet use and different types of use might have negative effects on social involvement with family and friends. Such studies focused on the well-being of Internet users. These studies were based on the social displacement hypothesis, which argues that time spent online displaces everyday social interaction with family and friends, and that social isolation has negative implications for users' psychological well-being. Early studies of Internet users' time online presented some evidence supporting this argument (Kraut et al., 1998; Nie, 2001). However, subsequent investigations showed that the effect appears to differ according to personality orientation and initial levels of social resources such as perceived social support, network size, and extraversion (Katz and Rice, 2002; Wellman et al., 2001; Bessière et al., 2008). A 'rich get richer' hypothesis explained these differential effects, indicating that very sociable individuals embedded in extensive networks of social support derive more social benefit from using the Internet. Very sociable people reach out to others on the Internet and use it particularly for communication. In contrast, individuals with lower levels of social support and more circumscribed social networks turn to the Internet to compensate for their lack of social resources. However, they do not reap the same level of benefits from online interpersonal communication and continue to suffer from social isolation and a poor sense of well-being (Bessière et al., 2008).

Later investigations failed to replicate the earlier findings. Indeed, studies have found no evidence that Internet use reduces social involvement (Rice and Katz, 2000; Wellman et al., 2001). Furthermore, some studies even suggested that Internet users tend to report more social involvement than non-Internet users do. Thus, several critiques have been leveled against the displacement argument (Gershuny, 2003). One criticism notes that Internet use does not necessarily come at the expense of other activities. This position rejects the idea that time is fixed. Second, the Internet facilitates information searching, communication, game playing, file downloading, and other activities, providing a technological infrastructure for a more efficient way of conducting these activities and thereby freeing up time for more social involvement. According to this view, individuals use these communication tools primarily to reinforce existing relationships with family, friends, and romantic partners. They are increasingly integrating these tools into their off-line worlds, for example, by using social networking sites to get more information about new entrants into their off-line world (Subrahmanyam et al., 2008).

Another criticism rejects the assumption that Internet use is a solitary activity, conducted alone and without the involvement of others. In fact, according to this view most Internet use is social. Rather than isolating the user, the Internet facilitates interpersonal contact, so that users may actually be more socially involved than others (Wellman et al., 2001). Finally, most of the early studies used only a single item to measure ICT use, namely, self-reported frequency of use. This single measure does not account for different uses of information and communication technologies. While some of these uses such as online gaming may be conducted in isolation, others allow one to connect and reconnect with acquaintances, family, and friends, expanding one's social circle. More recent studies have focused on the use of the Internet for information seeking, for entertainment, and for communicating with family and friends. These studies report an association between one's initial social resources, the type of Internet use, and the social outcomes (Shah et al., 2001). Individuals reporting high levels of social support and large social networks were more likely to use the Internet for communicating with family and friends. In contrast, individuals reporting lower levels of social support were more likely to use the Internet for entertainment purposes and for meeting with unknown others. All of the respondents used the Internet quite frequently to find information, and there was no association between this activity and previous levels of social support (Bessière et al., 2008). Studies also report an association between the types of Internet use and an individual's well-being. Using the Internet for entertainment was correlated with higher levels of perceived depression, whereas using the Internet for communicating with friends and family was correlated with lower levels of depression. Using the Internet for information search was uncorrelated with depression. These findings highlight the fact that the Internet is a multipurpose technology with a wide range of uses. Furthermore, one's initial social resources shape one's reasons for using the Internet. These various uses, in turn, may have different effects on one's well-being, social engagement, and involvement in social activities (Bessière et al., 2008).

Involvement in social networks is one of the central dimensions of social capital. Studies have established an association between social media use and network size and heterogeneity. Social media use is also associated with social capital because formal and informal conversations are important for exposure to nonredundant information, ideas, and opinions (Hampton et al., 2010; Hargittai and Hsie, 2010. Regarding the size of core networks, studies have found that using different social media applications such as instant messaging, social networking sites, and weblogs is not associated with a decrease in the size of one's core networks (Mazur and Richards, 2011). Furthermore, a study based on a large

representative sample of the US population found some indications that regardless of the application being used Internet users did not report larger networks, but were more likely to report greater heterogeneity in their core discussion networks (Hampton et al., 2010). Network heterogeneity is associated with the extent of overlap of the origins of one's social ties, whether online or off-line. The networks in applications such as instant messenger and social networking sites generally tend to be homogeneous and reflect off-line networks. In a study of preadolescents that compared the networks of 'friends' in social networking sites, instant messaging, and face-to-face communication, the results showed that there was a partial but substantial overlap between participants' online and off-line networks. Half of the closest instant messaging friends' names were also listed as the respondents' closest face-to-face friends, and 49% of the respondents' face-to-face friends were also the top social networking site friends. Thus, there is a large overlap between off-line and online worlds (Subramanyam et al., 2008).

Another study of adolescents (ages 16–19 years) used interactions in the public space of a social networking site ('the wall') as the unit of analysis and investigated whether the characteristics of online 'friends' were similar to or different from the characteristics of the young social networkers themselves. The study found that on average more than half of the interactions were with others who belonged to the same ethnic group, and 42% were with others of the same gender. In addition, the majority of the interactions reported were with similar others in terms of age category and place of residence (Mazur and Richards, 2011).

Other studies have investigated the extent to which social media is used to support existing ties or develop new social ties. In a study about the use of instant messaging, researchers found that it is generally used to support strong ties rather than weak ties (Mesch et al., 2012). In contrast, chat rooms and weblogs are often used for communication with those with whom one has weak ties rather than strong ties (Hargittai and Hsie, 2010).

Furthermore, more intense users of social media engage in more social activities on social networking sites than those who spend less time on such sites and use only one site. There are differences according to gender, as women pursue stronger tie activities than do men, such as interacting with existing friends. However, women engage in fewer weaker tie activities than men do, such as developing new relationships via these sites (Hargittai and Hsie, 2010).

In sum, the empirical evidence indicates that social media is a complementary communication channel that is used with existing social ties. Individuals tend to bring their existing connections to the social networking sites. The level of one's social resources is an antecedent of social media use. Those with high levels of social support and social involvement are the ones who gain the most from the use of social media. The use of social media may expand one's network size and increase its heterogeneity, but only modestly.

Collective Level Studies

On the collective level, research has focused on the use of social media use, civic engagement and political participation. Putnam (1993: p. 90) argued that "participation in civic organizations inculcates skills of cooperation as well as a sense of shared responsibility for collective endeavors." Indeed, early studies investigated the role of the frequency of use of social media on civic engagement and community involvement, with some of these studies reporting a negative relationship between the two (Kraut et al., 1998; Nie, 2001).

Nevertheless, there are grounds for assuming that different types of Internet use may have different effects on network diversity, interpersonal trust, and civic engagement. Information searching may promote civic engagement, because through such searches users gain knowledge about social and community issues, build connections, and coordinate their actions to address mutual concerns. Thus, searching for information online exposes the user to opportunities for participation in civic life, and may encourage citizens to participate in more and find more opportunities to contribute to society.

At the same time, using the Internet for entertainment does not provide the benefits of acquiring new information and making connections with new contacts for collective action. Online recreation consumes time and energy without providing opportunities to become involved in community or civic activities and may even weaken one's links to existing social ties. Various studies suggest that civic and social engagement is dependent on the type of Internet use. While informational use is positively associated with civic engagement, defined as participation in civic and community affairs, Internet use for social recreation has a small negative effect on interpersonal trust and does not affect civic engagement (Shah et al., 2001). These findings were also confirmed in longitudinal studies that compared the level of civic engagement of a 1965 high school class cohort before and after the adoption of the Internet. The study found that Internet access and its use to follow public affairs was positively associated with indicators of political involvement. It also established a strong relationship between Internet use and membership in voluntary organizations. It is very likely that early adopters of the Internet had an a priori tendency to be involved in civic and political affairs. Nevertheless, even controlling for previous civic involvement, the findings support the idea that Internet use for information access adds to the indicators of civic engagement and membership in voluntary associations (Jennings and Zeitner, 2003).

Using a large sample of the American population, a study that investigated the association between different social media applications and civic engagement in social and voluntary associations found that the effects differed according to the application. The use of weblogs increased participation in voluntary groups, participation in picture sharing social network sites, and increased participation in public spaces, and the use of social networking sites increased participation in locally based activities (Hampton et al., 2010).

One explanation for the variation in effects may be the fact that different online platforms fulfill different social functions. For example, weblogs are places of interaction in which users maintain their anonymity by using nicknames and are more likely to interact with others who might not be known to them and may reside in a different city, state, or country. One study found a positive association between writing a weblog and having a more diversified personal network (Marlow, 2005).

Given that the context of the weblog interaction is based on mutual, emotional, or intellectual interests, much of the interaction is with unknown individuals who share concerns, hobbies, or other interests (Subrahmanyam et al., 2008). In contrast, instant messaging provides text-based, near-synchronous communication between two or more users who are usually known to one another. In addition to supporting peer interaction, instant messaging is used to support communication with family and romantic partners. Indeed, the use of instant messaging for meeting new contacts is unusual (Mesch et al., 2012).

Social networking sites allow users to present information about themselves (such as age, gender, location, education, and interests), encourage users to link to known and likeminded users whose profile exists on the site, invite known and like-minded individuals to join the site, establish and maintain contact with other users, post content, create a personal blog, and participate in online groups (Boyd and Ellison, 2007). Social networking sites are used for communication between individuals who have some knowledge of one another and belong to the same social circle or to the social circle of their friends (Steinfeld et al., 2008).

Steinfield et al. (2008) found that the intensity of Facebook use was associated with changes in users' social capital. Among college students scoring higher on the scale was related to increases in one's social capital. In addition, social networking sites may act as mediators between dispersed groups. Social networking sites facilitate social awareness and social interaction, and allow the maintenance of ties that otherwise might be latent or dormant. Through intensive participation in social networking sites, individuals may have greater access to informational, emotional, and tangible support. Furthermore, participation in social networks enables individuals to develop norms of trust and reciprocity, which are necessary for successful engagement in collective activities. Studies on the effects of the use of the social network on trust and participation in civic and political activities among college students found that intense use of Facebook was associated with greater trust and participation in civic and political activities (Valenzuela et al., 2009).

Social networking sites can also be used for a variety of activities, such as one-to-one communication, broadcasting to a wider audience, and the passive consumption of news. Direct communication with individual friends consists of personal, one-to-one exchanges. On the other hand, social broadcasting refers to the updating of one's personal status and the posting of content for the consumption of unlimited others, while the passive consumption of news refers to browsing through the posts of other users. Thus, the use of social network sites for direct one-to-one communication and passive consumption of news appears to be associated with higher levels of social capital.

Social Media and Trust

Social capital is strongly interconnected with the concept of trust (Best and Krueger, 2006). Trust can be defined as the willingness to accept a vulnerable situation based on positive expectations about the actions of others. When social players do not trust others and do not feel that other players trust them, cooperation is unlikely. Trust is usually higher among individuals who participate in networks of social engagement (Blanchard and Horan, 1998).

Online trust is a difficult goal to achieve because it requires the establishment of trusting relationships in the online world. The Internet itself is an object of trust with uncertain conditions just because it is not based on dyadic or group relations alone (Wang and Emurian, 2005). Internet users perceive the online world as one in which they are uncertain about the risks and results of their online transactions. For this reason, the online environment is viewed as insecure. Studies of online self-disclosure have shown a direct relationship between trust in online providers and self-disclosure. Users tend to adjust how much information they disclose based on a consideration of perceived risks and trust (Joinson et al., 2010). Studies have also investigated the association between Internet use and trust. Early studies examined the extent to which Internet use promoted interpersonal trust and reported that Internet users were no more likely than nonusers to report interpersonal trust. However, trusting people are more likely to use the Internet for shopping and less likely to believe that their privacy will be violated online (Uslander, 2004).

As to the association between online and off-line trust and its effect on the disclosure of personal information, the Internet attribute approach implies that the attributes of the Internet (relative anonymity, lack of sufficient cues, and controllability) generate online behavior that is independent of off-line behavior. According to this approach, the structural attributes of the Internet encourage interactants to engage in more intimate exchanges in online settings than in face-to-face settings. Fewer nonverbal cues and greater controllability reduce people's inhibitions when interacting online, perhaps leading to the rapid development of online trust that in turn may lead to increased online self-disclosure. According to the Internet attribution approach, the ability of the Internet to free one from inhibitions will be positively associated with both the development of online trust and the disclosure of identifiable information. It is important to note that according to this approach, online trust is not associated with trust in individuals or trust in institutions, but develops as a result of the attributes of the online environment.

In sum, studies that have investigated the role of Internet use and social media have established that the acquisition of social capital differs according to the type and purpose of the social media one uses. Using social media to access information and enhance one's social ties improves one's level of social capital. At the same time, research has not established whether this association is a causal effect or the result of common antecedent variables. Some studies link one's level of initial social resources with the types of Internet and social media one uses, determining that when controlling for initial resources, the gain in social capital may be modest. This line of research requires more attention in the future. In addition, while the Internet is a global technology, the vast majority of the studies have been produced in only one country. As the use of social media spreads to a growing number of countries, comparative studies are required to be able to generalize the findings of existing research.

New Media and the Digital Divide

Alexander van Deursen and Jan van Dijk, University of Twente, Enschede, The Netherlands

Abstract

During the 1990s, researchers and policy makers began discussing the presence of a so-called 'digital divide,' a distinction of people who do and do not have access to information and communication technologies. The concept of the digital divide stems from a comparative perspective of social and information inequality and depends on the idea that there are benefits associated with ICT access. Originally, the digital divide was defined in terms of physical access to a technology. This is now considered superficial and the emphasis is shifting to new dimensions, that is, inequalities of skills and usage.

Introduction: The Digital Divide Concept

During the 1990s, researchers and policy makers began discussing the presence of a so-called 'digital divide,' a distinction of people who do and do not have access to information and communication technologies (ICTs). The concept of the digital divide stems from a comparative perspective of social and information inequality and depends on the idea that there are benefits associated with ICT access and usage and negative consequences attending non-access and usage. Originally, the term 'digital divide' mostly referred to gaps in access to computers. When the Internet became widely accessible in society and began to provide a primary means of computing, the term shifted to encompass gaps in Internet access. Defining the digital divide in terms of access to the Internet is now the most popular convention. However, other digital equipments such as mobile telephony and digital television are not ruled out by some users of the term digital divide.

The term digital divide probably has caused more confusion than clarification. According to Gunkel (2003), it is a deeply ambiguous term in the sharp dichotomy it refers to. van Dijk (2005) has warned against a number of pitfalls of this metaphor. First, the metaphor suggests a simple divide between two clearly divided groups with a yawning gap between them. In fact the divide is more like a spectrum with people who use computers and the Internet for about every daily task on the one side and the people not using them at all on the other. Secondly, it suggests that the gap is very difficult to bridge. A third misunderstanding might be the impression that the divide is about absolute inequalities, which is between those included and those excluded. In reality most inequalities of the access to digital technology observed are more of a relative kind (see below). A final wrong connotation might be the suggestion that the divide is a static condition while in fact the gaps observed are continually shifting.

An important theoretical distinction concerned is that between individualistic and relational conceptions of social inequality. The first conception departs from so-called methodological individualism (Wellman and Berkowitz, 1988). Differential access to information and computer technologies (ICTs) is related to individuals and their characteristics: level of income and education, employment, age, sex, and ethnicity, to mention the most important ones. This is the usual approach in survey research, which measures the properties of individual respondents. Making multivariate analyses of several individual properties and aggregating them to produce properties of collectivities, one hopes to find background explanations. An alternative notion of inequality uses a relational or network approach (Wellman and Berkowitz, 1988). Here, the prime units of analysis are not individuals but the positions of individuals and the relationships between them. Inequality is not primarily a matter of individual attributes but of categorical differences between groups of people. This is the point of departure of the pioneering work *Durable Inequality* by the American sociologist, Charles Tilly (1999). "The central argument runs like this: Large, significant inequalities in advantages among human beings correspond mainly to categorical differences such as black/white, male/female, citizen/foreigner, or Muslim/Jew rather than to individual differences in attributes, propensities, or performances" (Tilly, 1999: p. 7). In this conception gender inequality in using ICTs, for example, is not explained by the presumed characteristics of males and females (females having less technical interest etc.) but by the gender relations between them in which males first appropriate new technologies and exclude females in daily practice.

Despite these conceptual problems the term 'digital divide' drew attention to the important issue of information inequality in scholarly and political communities at the turn of the century. Countries increasingly realized that the digital divide reduces the potential of the labor force and innovation. Information and communication technologies were considered to be a growth sector in the economy that should be supported in global competition. Between 2000 and 2004, scientific and policy conferences concerning the digital divide were exceedingly popular, but attention to this matter began to decline in 2004 and 2005 (van Dijk, 2006). On political and policy-making fronts, many observers, particularly those in rich, developed countries, reached the conclusion that the problem was almost solved, as a rapidly increasing majority of their inhabitants obtained access to computers, the Internet, and other digital technologies.

The common current opinion among policy makers and the public at large is that the divide is closing between those who do and do not have access to computers, the Internet, and other digital media. In some countries, Internet connection rates in households have reached the figure of 90%. Computers, mobile telephony, digital televisions, and other digital media are becoming cheaper by the day, while their capacity to

perform complex tasks increases. These media are introduced on a massive scale and into all aspects of everyday life. Several applications appear so easy to use that basic literacy supposedly is the sole prerequisite for using them. However, simultaneously defining the digital divide in terms of physical access to a technology is considered superficial by digital divide researchers; physical access alone is no longer considered to be the most important factor explaining information superiority observed. The emphasis is shifting to new dimensions, which is inequalities of skills and usage.

Dimensions of the Digital Divide

First Dimension: Physical and Material Access

An important reason for the decreasing attention given to the digital divide in the first decade of the twenty-first century lies in the fact that divides in physical access to the Internet are closing in most Western countries. Concerns about acquiring physical access to digital media have completely dominated public opinion and policy perspectives in the last two decades. Indeed, these concerns are still paramount, as many people think the digital divide is closing because 90% of the population or more have access to computers and Internet. Such a number would put the Internet on par with television as a media source. One should note that the diffusion of the Internet in the past two decades has occurred even faster than that of television. However, on a global scale the situation is different; in 2010 Internet access was estimated between 20 and 25% of the world population, while in many developing countries, Internet access is still restricted to less than 10% of the population (UN/ITUstatistics).

Moreover, physical access is not equal to material access. Material access includes all costs related to the use of computers, connections, peripheral equipment, software, and services. These costs are diverging in many ways, and people with physical access have very different computer, Internet, and other digital media expenses. Considering the current economic crisis in the Western world, the problem of material access to computer and Internet resources for particular parts of the population might become more serious. In this regard, several scholars have pointed toward mobile phones and other portables such as tablet computers as technologies that have the potential to reduce the digital access divide. Mobile phones offer a more affordable means of access to the Internet than computers do when only simple applications that require small data capacity are used (Akiyoshi and Ono, 2008). They are supposed to offer a viable alternative for developing countries. However, one should also keep in mind that mobile phones are by no means a substitute for computers as they lack many advanced applications.

Whatever opportunities mobile phones offer, it is certainly a misconception to think that physical or material access to the Internet automatically brings all the benefits associated with Internet use. Indeed, it is rather schematic and superficial to conceive the digital divide in terms of a binary classification between those with and without physical access to computers or the Internet. Such a belief directly links rates of access to differences in material resources: one either does, or does not, have the resources to establish a connection to the Internet. Moreover, such a belief assumes that having a connection correlates with having access to all the advantages the Internet offers. Compaine (2001), for instance, relied on the Diffusion of Innovations (DI) theory of Everett Rogers (1963/1995), who theorized that innovations would spread through society in an S-curve. The S-curve measures the relative speed with which members of a social system adopt a particular innovation and focuses on the time required for that innovation to be adopted by a certain percentage of the system (Rogers, 1995). The adoption rate accelerates at a first tipping point, called critical mass; at this point, an innovation has been so widely adopted that its continued adoption is self-sustaining (Markus, 1987). At a second tipping point diffusion begins to slow down as the market starts to reach saturation. Here, the access divide starts to close. van Dijk (2012) has portrayed the current situation of the physical access divide on a world scale in terms of the S-curve with the locations of developed and developing countries mapped into it.

The two curved lines in **Figure 1** are splitting the main curved line that has the shape of an S to indicate that we have two sides or populations in the digital divide with different representations of the S-curve (that portrays the average). One curve is for those on the 'wrong' side of the digital divide, usually people with low education, low income, and higher age; and the other is for those on the 'right' side of the divide, mostly people with high education, high income, and lower age. When the two lines come together, the physical access divide is closing. However, at this point in time we still do not know whether it will close completely, called 'normalization' in the figure, or that a gap will remain because the social categories in the higher curve continue to have a lead because they first adopt every new innovation in the field of digital media (e.g., the transition from narrowband to broadband), which is called 'stratification' by Norris (2001).

If Compaine and van Dijk were correct in applying DI theory to the digital divide, increases in physical access to the Internet would no doubt correspond to the S-curve measuring

Figure 1 Evolution of the digital divide of physical access in time. Line below: access of categories of low education, low income, and higher age. Line above: access of categories of high education, high income, and lower age. Source: van Dijk, J.A.G.M., 2012. The evolution of the digital Divide. In: Brus, J., Crompton, M., Hildebrandt, M., Metakides, G. (Eds.), Digital Enlightment Yearbook 2012, IOS-Press, Amsterdam, pp. 57–75.

the adoption of innovations. From this point of view, the digital divide should steadily disappear as the diffusion rate reaches saturation, particularly when 'normalization' applies. The likelihood of the correspondence between the declining digital divide and the increasing rate of innovation diffusion would further be augmented as a result of the migration of the Internet to platforms such as digital television and mobile phones; indeed, the mistaken notion that the digital divide is a temporary problem of physical access has been reinforced by these migrations (Golding and Murdock, 2001). However, there are serious problems with applying the DI theory to the study of computer and Internet diffusion (Norris, 2001; van Dijk and Hacker, 2003). van Dijk (2005: pp. 62–65), which mentions several weak assumptions of this theory. First, why should the diffusion of each medium necessarily reach a 100%? Instead of this 'normalization' it might stop far before the stage of population-wide diffusion or become stratified (some categories keep adopting more and earlier than others). Secondly, while the DI theory assumes the existence of a single confined medium that does not change, in fact digital media devices often are combined (multimedia) and they continually change in functionality, quality, price, and appearance (think about the history of the PC). Finally, the determinism of DI theory is striking: why should there be innovators, early adopters, and early or late majority users with every medium?

Other Dimensions Come Forward: The Second-Level Digital Divide

Because it is wrong to assume that physical access to computers and the Internet automatically entails all benefits associated with their use, the digital divide should not be considered as a divide of physical access only. In the literature about the digital divide published after 2000, this conclusion comes forward stronger and stronger. Other dimensions have also come forward. Kling (2000), for instance, suggested a distinction between technical access (i.e., material availability) and social access (i.e., professional knowledge and technical skills necessary to benefit from information technologies). Attewell (2001) distinguished between a first digital divide and a second digital divide. Hargittai (2002), however, suggested what has become perhaps the most familiar distinction: that between first- and second-level digital divides. Besides these dimensions Warschauer (2003) also argued that factors such as content, language, literacy, educational level attained, and institutional structure must be considered. van Dijk (2005) proposed a causal model with four types of access to ICTs: motivational access (e.g., the lack of the elementary digital experience by people who have no interest or feel hostile toward ICTs), physical access (e.g., the availability of ICTs), digital skills (e.g., the ability to use ICTs), and usage access (the opportunity and practice of using ICTs). He calls the shift from physical access to skills and usage a 'deepening divide' as unequal skills and usage are deeply entrenched in existing social inequalities and because they will deepen these inequalities further.

The Dimension of Motivation

Each of these scholars shares the following view: while gaps in physical access might be closing in certain respects, other digital divides have begun to grow. In his discussion of motivation access, for instance, van Dijk (2005) argues that the wish to have a computer and a connection to the Internet precedes physical access. Thus, many of those who remain on the excluded side of the digital divide do so for motivational reasons. According to van Dijk, there are not only 'have-nots' but also 'want-nots.' At the start of the diffusion of new technologies, motivational concerns are the strongest forces to stimulate or prevent the acceptance of those technologies. In several European and American surveys conducted between 1999 and 2003, half of those individuals unconnected to the Internet explicitly stated that they would refuse to seek a connection for the following reasons: no need or significant usage opportunities, no time or liking, rejection of the medium (e.g., Internet and computer games viewed as 'dangerous' media), lack of money, or lack of skills (e.g., ARD-ZDF, 1999b and a Pew Internet and American Life survey: Lenhart et al., 2003). These observations lead us to one of the most confusing myths produced by popular ideas about the digital divide: that people are either in or out, included or excluded. To explain people's motivations for using digital technologies, mental and psychological conditions are often mentioned in literature about the digital divide. Here, the phenomena of computer anxiety and technophobia are still relevant and continue to create barriers to computer and Internet access in many countries, especially among seniors, people with low educational background, and segments of the female population (Brosnan, 1998; Chua et al., 1999; Rockwell and Singleton, 2002; UCLA, 2003).

The Skill Dimension

In contemporary literature, inequality of Internet skills is increasingly acknowledged as a key dimension of the digital divide. Several terms are used to frame Internet skills, e.g., digital or information literacy, computer skills, ICT literacy, or web fluency. To date, very little scientific research has focused on the actual level of digital skills possessed by various populations. Many large-scale surveys have revealed dramatic differences in skills among populations, including those populations in countries experiencing the extensive diffusion of new media (van Dijk, 2005; Warschauer, 2003). Nevertheless, these surveys measure actual levels of digital skills only by asking respondents to estimate their own proficiency.

A better way to obtain valid and complete measurements of digital skills is to implement performance tests; such tests would require participants to perform those computer and Internet tasks that are regularly performed in daily life. Hargittai (2002) has begun to implement performance tests in this field. Asking 54 demographically diverse Americans to perform different Internet search tasks, she discovered enormous differences in the levels of accomplishment and in the time needed to complete the tasks. In the Netherlands, van Deursen and van Dijk (2010, 2011) conducted performance tests in a university media laboratory on a cross-section of the Dutch population; more than 300 people were tested. Subjects who took the test showed a fairly high level of basic operational and formal skills, but they experienced much more difficulty in processing content-related information and in exercising strategic skills.

The results showed significant differences in performance between people of different ages and levels of education. Age primarily appears to be a significant contributor to the basic skills to use the Internet medium-related skills, as younger people perform better on these skills than that of older people. In contrast, older individuals performed better where content-related skills, including information and strategic skills, were needed; this occurred in all instances where the older individuals possessed an adequate level of medium-related skills. However, because many seniors tend to lack medium-related Internet skills, they are seriously limited in their content-related skills. Nevertheless, this observation provides another perspective on popular notions about the abilities of the so-called 'digital generation.' It also shows that the skills inequality problem will not automatically disappear in the future, and that life experience and substantial education of all kinds remain vital for acquiring digital skills.

The Usage Dimension

Aside from divergences in skill levels, the digital divide debate has increasingly drawn attention to the actual usage of the Internet. As a dependent factor, Internet use can be measured in several ways (e.g., usage time and frequency; number and diversity of usage applications; broadband or narrowband use; more or less active or creative use). Statistics regarding usage time and frequency are notoriously unreliable, as they rely on shifting and divergent operational definitions that are often determined by market research bureaus. These statistics give only some indication of the difference between actual use and physical access. It is certain, for example, that actual use diverges greatly from potential use. Furthermore, those who have a computer and/or Internet connection not always actually use them. Many assumed users actually use the computer or the Internet only once a week or a few times a month; some people never use them.

It is important to understand that when a physical access gap for a particular social category closes, usage of the medium concerned does not automatically equalize. Here the concept of 'usage gap' might apply. This concept is comparable to the concept 'knowledge gap' created in the 1970s by Tichenor et al. (1970). While the knowledge gap concerns the differential derivation of knowledge achieved through mass media and focuses, in particular, on mass media's influence on perception and cognition, the usage gap concept is much broader and potentially more effective in terms of social inequality because this gap concerns differential uses of and activities with computers and the Internet in all spheres of daily life, not just the derivation of knowledge.

The usage gap closure becomes most apparent when looking at types of usage. It is generally assumed that some Internet activities are more beneficial or advantageous for Internet users than others. Some activities offer users more chances and resources to move forward in their career, work, education, and societal position than others that are mainly consumptive or entertaining (e.g., Hargittai and Hinnant, 2008; Kim and Kim, 2001; Mossberger et al., 2003; van Dijk, 2005; Wasserman and Richmond-Abbott, 2005). In terms of the theories of capital inspired by Bourdieu (1984), one could also say that certain Internet activities allow users to accrue more economic, social, and cultural capital and resources than other activities. While some sections of the population will more frequently use those applications that have the greatest advantages for accruing capital and resources (such as work, career, study, and societal participation), other sections will choose to use those entertainment applications that have little or no advantage for accruing capital and resources (e.g., van Dijk, 1999; Bonfadelli, 2002; Park, 2002; Zillien and Hargittai, 2009).

These differences in types of Internet use call into question the belief that growing up in a digital world results in an intuitive and unproblematic use of digital technologies (see Prensky, 2001). A difference exists between the personal and purposeful uses of technologies such as the Internet. Recently, several scholars have addressed the digital divide by attempting to classify Internet usage types. Some of these classifications take the uses-and-gratifications approach (Katz et al., 1974) as a starting point, while others make use of the Technology Acceptance Model (Davis, 1989) or Social Cognitive Theory. Finally, there are scholars who account for differences in usage by grouping Internet users into use typologies (e.g., Ortega Egea et al., 2007).

The Digital Divide and Inequality

What is the stake or concern of the digital divide? Do people with no access or limited access actually experience disadvantages? Two contra-arguments are given frequently by people relativizing the importance of the digital divide. The first argument is that people still have the traditional media at their disposal, which also deliver information and provide the needed communication channels. For those who have no Internet, a multitude of broadcasting and print media is available, and for those who have no access to e-commerce, physical shops abound. People searching new social contacts or romantic encounters do not necessarily require a social-networking site or an online-dating service, as the choice of physical meeting places is immense. Those individuals who want to make a reservation can still pick up the phone. The second argument is that the nonhierarchical nature of the Internet, in conjunction with the declining cost of computing technologies and their increasing user friendliness, encourages social leveling and undermines existing patterns of class, race, and gender inequalities (see Tambini, 2000).

However, after the times of the Internet hype around the turn of the century most scholars now agree that differences in Internet access among segments of the population tend to reinforce social inequalities. Witte and Mannon (2009), for example, argue that the Internet is both intertwined with and consequential for inequality. Considering the Internet in a paradoxical way, they contend that it is not only an exemplar of a free and open society but also an active reproducer and potential accelerator of social inequality. To understand this paradox one has to realize that the digital divide is more characterized by relative than by absolute inequalities (see Introduction). The digital divide signifies a spectrum of positions of inclusion and exclusion, not a binary classification of absolute inclusion and exclusion. Ninety percent or more of a population might have access to computers and the Internet, while social and information inequality continue to rise on account of unequal material access, digital skills, and usage opportunities.

A classification of resources suggested by Bourdieu (1984) is often mentioned in discussions of the Internet's contribution to inequality. Bourdieu reimagined both Marx and Weber's ideas of social inequality in industrial society by defining economic, cultural, and social capital. Economic capital reflects Marx's ideas of property assets and other economic inequalities such as particular positions in the relations of production that might increase one's capacities (Hoffman, 2008). Meanwhile, social capital consists of resources based on group membership, relationships, networks, and support; according to Bourdieu, social capital "constitutes the totality of current and potential resources connected to a durable network of more or less institutionalized relations characterized by mutual knowing or acknowledgments; in other words, social capital is a resource based on the affiliation to a group" (Bourdieu, 1984: p. 190). Finally, cultural capital is formed by knowledge, skills, education, and social–cultural distinction, all of which give a person a higher status in society.

All forms of capital defined by Bourdieu are applicable to the Internet. In fact, Internet use and Bourdieuian forms of capital reinforce each other. On the one hand, all forms of capital affect Internet access: economic capital is a requisite to acquire physical and material access to computers and the Internet; social capital is needed to learn from others how to connect to the Internet, how to use it, and how to connect to those others; finally, cultural capital is required to cope with the diversity of content available to people of different cultural backgrounds. On the other hand, when these three requirements are met, the Internet in turn starts to affect the three forms of capital. For example, economic capital is increased by buying profitable resources online or by finding better jobs; social capital can be augmented by extending physical networks into virtual ones, perhaps increasing civic engagement and a sense of community (Katz and Rice, 2002); and cultural capital can be increased by using the Internet for learning purposes.

The result of the mutually determining relationship between forms of capital and the Internet is the usage gap discussed before which means that some individuals use the Internet in capital-enhancing ways, while others either do not use it or use it in less effective and less profitable ways; and the Internet may, of course, also be used simply for leisure (Hargittai and Shafer, 2006; Zillien and Hargittai, 2009). Furthermore, the intensive and extensive nature of Internet use among the well-off and well-educated correlates with an elite lifestyle, one from which those with less capital are excluded (van Dijk, 2005; Witte and Mannon, 2009). The result of this last observation is that groups with fewer forms of capital are likely to be affected in negative ways by the Internet: flights will be booked, concerts will be sold out, jobs will be given away, and dates will primarily be granted to those having access. This is the main counter-argument against the argument that traditional channels still offer all opportunities mentioned above. Rather than encouraging equality, the Internet tends to reinforce social inequality and can lead to the formation of more permanent disadvantaged and excluded groups, unless deliberate economic, cultural, and educational policies are installed by responsible policy makers (Golding, 1996; van Dijk, 2005). As Witte and Mannon (2009) contend, Internet access can be understood as a tool for the maintenance of class privilege and power as the inequalities upon which they rest are reproduced from one generation to the next.

Much theoretical work on the concept of network society also suggests that the Internet increases social inequalities. Castells (1999) considers the divide between those who are and are not networked as one of the major axes of social inequality (Castells, 1999). He contends that the particular framing of ICTs in the context of global, informational, and increasingly deregulated capitalism has been a major factor in the increase of inequality, in general, and of social exclusion, in particular. Because technological access is essential for both the improvement of living conditions and personal development, ICTs deepen discrimination and inequality in the absence of deliberate corrective policies (Castells, 1999).

van Dijk (1999, 2006, 2012) defines the network society as a form of society that organizes its relationships into media networks; these networks gradually replace or merge with the social networks of face-to-face communication. For van Dijk, media networks have become the nervous system of society and are shaping the primary means of social organization and the most important structures of modern society. In a network society, information should be considered a positional good, with some positions creating better opportunities than others for gathering, processing, and using valuable information (van Dijk, 2005). The positions people have in networks determine their individual potential power; this concept reflects the Weberian idea that human relationships should be considered alongside economic assets when discussing social inequality. When someone in a network society has only a marginal position or no position at all, he or she experiences social exclusion because the opportunities are reduced. Meanwhile, those who have a central position in society achieve social inclusion and thereby increase their power, capital, and resources (van Dijk, 2005). With unequal positions comes an unequal distribution of positional goods. According to the mechanism of opportunity hoarding, those individuals who have central positions in networks tend to appropriate more goods, to exert more control over particular facilities, and to wield greater power within networks; they then capture the returns of these resources and use them to reproduce the boundary between themselves and those who are socially excluded (Tilly, 1999).

In conclusion, most recent scientific literature on the digital divide suggests that the Internet has the potential to strengthen traditional kinds of inequality rather than to ameliorate them. Unequal access to the Internet has varying consequences in several areas of society: the economic (e.g., acquisition and maintenance of jobs), the social (e.g., development and maintenance of social contacts), the political (e.g., voting and other kinds of political participation), the cultural (e.g., participation in cyberculture), the spatial (e.g., the ability to lead a mobile life), and the institutional (e.g., recognition and attainment of citizens' rights).

New Media, News Production and Consumption

Eugenia Mitchelstein and Pablo J Boczkowski, Northwestern University, Evanston, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews the scholarship on online news consumption, addresses the limitations of this scholarship, and proposes avenues for future inquiries. It examines the scholarship in five areas: displacement and complementarity between traditional and online news consumption; audience fragmentation and homogenization; online news and political knowledge; Internet information as a resource for participation; and the user as a content producer. The assessment suggests that while audiences have straddled between tradition and transformation in their news consumption practices, most scholarly examinations have been characterized by stability rather than innovation.

Citizens in modern societies routinely engage in news media consumption. Since the mid-1990s, online news has been incorporated into the media diets of large segments of the population. In December 2011, four of ten Americans reported getting most of their national and international news from the Internet (Project for Excellence in Journalism, 2012). As online news audiences have expanded and become mainstream, research on online news consumption has increased and consolidated. However, but for a few exceptions (Boczkowski, 2002; Mitchelstein and Boczkowski, 2010), there have been few comprehensive analyses of the findings presented by these studies, and of the new directions research should take to contribute to a more thorough understanding of the manifold aspects of the phenomenon. This article aims to fill those two voids by providing first, a review of the literature on new media and news consumption published so far; and second, by addressing the main limitations in the existing scholarship and proposing new avenues for future inquiries. Building upon a prior article (Mitchelstein and Boczkowski, 2010), this article accomplishes these two goals by examining the research on five key areas of scholarship: the relationship of either displacement or complementarity between traditional media and online news consumption; audience fragmentation and homogenization; the link between online news access and political knowledge; Internet information as a resource for civic participation; and, the user as a content producer. Our assessment suggests that while audiences have straddled between tradition and transformation in their daily news consumption practices, most scholarly examinations have been characterized by stability rather than innovation, which may have obstructed a thorough assessment of the balance between steadiness and variance in online news consumption.

Does Online News Consumption Complement or Displace Traditional Media Consumption?

The widespread adoption of online news consumption has triggered studies on whether Internet news use complements or displaces traditional sources. One camp of scholarship proposes that online news consumption complements access to information in traditional media. For instance, Taneja and colleagues observe media use behaviors among more than 40 000 Americans and find that "that access to on-demand media (85% had home internet), does not displace linear television viewing" (Taneja et al., 2012: 964), which confirms the complementarity hypothesis. A different perspective draws on uses and gratification theory to propose that consumers' goals shape consumption more strongly than medium attributes, and thus, people who are interested in news tend to access this content in the multiple platforms available to them (Yuan, 2011).

Based on the principle of relative constancy, the opposite camp argues that audiences' adoption of Internet news displaces their use of traditional media (Gaskins and Jerit, 2012). The 2010 Pew Biennial News Consumption Survey indicates that the portion of Americans who read a newspaper 'yesterday' fell from 38 to 26% between 2006 and 2010, whereas the percentage who accessed their news online rose from 23 to 34% in the same period (2010). Temporal, demographic, and socioeconomic factors shape the interplay between complementarity and displacement. Some authors propose that audience behavior changes over time, as the appropriation of online technologies is normalized (Althaus and Tewksbury, 2000). Research indicates that displacement effects are greater among better educated and younger users (De Waal and Schoenbach, 2010). This effect is particularly salient among the digital natives, many of whom have tenuous links to traditional media. Gaskins and Jerit argue that young users are not likely to "substitute the Internet for print news since they would not [give up] a habit they had not acquired in the first place" (2012: 202).

Some authors have linked adoption of online news to the perceived credibility of Internet information (Bucy, 2003; Tsfati, 2010). Yuan conducted a survey of Chinese news consumers and proposes that "the more credible the news users believed a medium to be, the higher the odds were for them to include it in their news media repertoires" (2011: 1007). Regarding media factors, some studies find that online news is more credible than news on television and radio, but less than that in newspapers (Flanagin and Metzger, 2000; Schweiger, 2000). Other research studies look at differences concerning the institutional affiliation of online news sites and conclude that users rate traditional media sites as more credible than independent sites. For instance, in a survey of college students in the United States, Chung, Nam, and Stefanone found that

they rated mainstream media sites as more credible than independent sites, and propose that these "news providers benefit from their extant offline reputation" (2011: 182).

Fragmentation and Homogenization among Online Media Audiences

Scholarship on Internet news consumption has also examined whether the proliferation of information sources online is tied to either fragmentation or homogenization of the audience. The first stream of research draws on selective exposure theory to propose that diversification in online news supply may lead to polarization as people obtain their information increasingly from, and discuss public affairs with, like-minded individuals (Sunstein, 2001). For instance, Stroud examined online information seeking behavior during the 2005 presidential campaign in the United States and found that "partisans were more likely to select likeminded Web sites" (2011: 59).

An alternative stream of research contends that there is little evidence of ideological fragmentation in Internet news media consumption (Brundidge, 2010; Webster and Ksiazek, 2012). Researchers who study online consumption patterns propose that a small set of relatively moderate mainstream news outlets get the largest share of the traffic, while ideologically-oriented sites receive much less attention from the audience (Hindman, 2009; Meraz, 2009). Gentzkow and Shapiro examine browsing behavior in the United States from 2004 to 2008 and find that "online news consumption is highly concentrated … the top 20 sites account for nearly 80% [of the visits]" (2010: 18).

Other analysts have proposed that increased content choice could lead to lack of attention to public affairs news among online news consumers (Boczkowski and Peer, 2011; Prior, 2007). However, Boczkowski and colleagues find higher levels of interest in public affairs online news articles during the 2008 presidential campaign in the United States than exactly a year later, and suggest that "engagement with public affairs issues might vary not only from person to person but also across temporal and contextual circumstances" (Boczkowski et al., 2012: 361).

The Consequences of Online News Consumption for Political Knowledge

Segmentation in online news audiences according to their level and type of attention to public affairs content raises the issue of whether access to online news fosters or hinders political knowledge. Scholars disagree on how best to characterize the relationship between Internet information consumption and information acquisition. Some researchers draw on Downs' economic theory of democracy (1957) to propose that the increased accessibility of online news makes it easier for citizens to access political information (Johnson and Kaye, 2003; Tewksbury and Rittenberg, 2009: 197).

But other researchers contend that increased availability of news content online might only increase access to public affairs content for those already engaged in political issues (Margolis and Resnick, 2000). Some scholars have drawn upon the knowledge gap theory to propose that the infusions of information have an uneven effect on citizen knowledge, as the population with higher levels of education tends to acquire this information at a faster rate than those with fewer years of schooling (Jerit et al., 2006). For instance, Yang and Grabe compare knowledge acquisition among South Korean citizens from different educational backgrounds, and conclude that "less educated people comprehended significantly more public affairs news from reading a newspaper than using an online source while more educated people delivered similar comprehension performances across the two media" (2011: 1223).

A different stream of research proposes that use of the Internet might increase the likelihood of unplanned news consumption, as consumers may increase their awareness about public affairs subjects when they are exposed to online information as a consequence of general Web use (Lupia and Philpot, 2005). Rainie and colleagues analyze survey data from the 2004 presidential campaign in the United States and find that "fully half of internet users (50%) said they encountered political news by happenstance browsing" (Rainie et al., 2005: 9).

Scholars have also analyzed whether exposure to online news is more or less conducive to learning political knowledge than use of traditional news media. Some studies show that online information consumption reduces knowledge and recall of current events (Althaus and Tewksbury, 2002; Dalrymple and Scheufele, 2007). Schoenbach, de Waal, and Lauf conduct a survey of the Dutch population and find that "reading print newspapers contributes to awareness of more public events and issues than using online newspapers does" (2005: 253). However, other research indicates that access to online news does not lead to a decrease in information acquisition when compared to traditional news media use (Drew and Weaver, 2006). Kwak and colleagues conducted a survey in Ann Arbor, Michigan, and found that "the Internet, as compared to television, was more useful to younger respondents in their understanding of international affairs" (Kwak et al., 2006: 203).

Online News as a Resource for Civic Engagement

Scholarship on the impact of online news consumption on democratic participation has fallen into two camps. The first one proposes that there are no significant links between online news consumption and civic participation (Margolis and Resnick, 2000). Drew and Weaver examine media effects during the 2004 presidential campaign in the United States and find that "internet news exposure/attention were not significant predictors of intention to vote after demographics, campaign interest, and traditional media exposure and attention were controlled statistically" (2006: 32). However, other studies have shown a positive relationship between access to online information and political engagement. Boulianne conducts a meta-analysis of research on the relationship between online news use and political participation and concludes, "increased access to a large, diverse set of political information may help reinvigorate civic life" (2009: 205).

A cognate area of research suggests that political discussion, both online and off-line, mediates the relationship between

online news use and political participation, as news consumers who talk about public affairs are more likely to increase their engagement with public affairs (Shah et al., 2007). Hardy and Scheufele propose that "people who seek information on the internet are more likely to engage in participatory behavior, with this effect being greater for those individuals who talk about politics with others regardless of the medium in which the discussion takes place" (2005: 81).

An alternative stream of scholarship views online discussion of public affairs as a form of civic participation, and proposes that online news media have lowered the cost of debating opinions in public (Etzioni, 2003; Papacharissi, 2004). However, studies of online discussion suggest that dominance of loud minorities, lack of rationality and civility in the exchanges, and exclusion of dissenting voices, hampers understanding (Boczkowski, 2010; Ruiz et al., 2011). For instance, Mitchelstein examines readers' motivations to comment on various online spaces and reports that posting comments in newspapers is related to self-expression goals, such as making opinions public and blowing off steam, while posting comments on blogs is linked to discussion and socialization motives. She adds that "participation in blogs appears to lead to higher perceptions of political competence than does participation in newspapers" (2011: 2014–2034).

The User as a Content Producer

Other analysts focus on audience members as producers of news content. Some scholars propose that, as consumers are able to participate in content creation, online news may become the result of a collaborative process between reporters and audience members (Boczkowski, 2004; Deuze, 2003). However, research has identified at least three limitations to user-authored news as a form of participation. First, some scholars suggest that news organizations are not enthusiastic about allowing audience members to become co-authors of content (Robinson, 2007). Singer and Ashman interview journalists at a British newspaper and find that they "expressed concerns about the credibility of user contributions, as well as the effects of uncivil comments on personal and institutional credibility" (2009: 18).

Second, research shows that bloggers and citizen journalists rely heavily on mainstream media for information. Meraz (2009) examines linking patterns of independent blogs and concludes that more than half of the outgoing links from independent blogs go to mainstream media sites. However, other scholars have found that, while user-generated journalism participates in the agenda-setting process, it neither follows the mass media agenda nor does it revolutionize the mainstream news dominated hierarchy (Anderson, 2010).

Third, scholarship on online news content indicates that members of the audience show limited interest in contributing content to online news sites. Robinson and Deshano interview people who had received training to produce content as citizen journalists in Madison, Wisconsin, and yet failed to do so, and report that "they were not confident that they could do 'journalism' on any level" (2011: 648). However, "for those who did begin contributing regularly, a richer sense of community followed participation" (2011: 654). Furthermore, research indicates that most user-generated content does not cover public affairs topics, but rather topics related to the contributors' personal life and interests (Ornebring, 2008). Gans indicates that citizen journalists "cover the informally organized parts of society, the 'private' worlds of family, friends, compatible neighbors, [and] work colleagues" (2007: 163).

Limitations of Previous Research

The previous sections have critically assessed recent scholarship on online news consumption, addressing five key research topics: whether it displaces or complements traditional media consumption; audience fragmentation and homogenization; the link between online news consumption and political knowledge; online news as a resource for civic participation; and, the user as a content producer. This assessment indicates that online news consumers straddle between tradition and innovation in their daily practices. Audiences have increased their use of online news but have failed to abandon traditional media as sources of information. They also exhibit a mix of fragmentation and homogenization in their content choices, and take advantage of increased content choice online to deepen their preexisting preferences toward either public affairs content or sports and entertainment news. Consumers forsake the opportunities offered by the web for increased civic engagement frequently but not always; and, for the most part, have not taken up the opportunities offered to create their own news. Thus, this account belies both reports of radical change in news consumption in the networked environment, and portrayals of online news audiences that engage in wholesale repetition of their off-line behaviors.

In a previous article (Mitchelstein and Boczkowski, 2010) we argued that most scholarship in this area has been characterized by stability rather than change, which may have interfered with a thorough assessment of the balance between tradition and transformation in online news consumption. These approaches have made significant contributions, but have also exhibited five important limitations: the assumption of a division between print, broadcast, and online media; the tendency to focus on either ordinary or extraordinary patterns of phenomena but not on both at the same time; the inclination to concentrate exclusively on online news, which hinders comparisons with previous media developments; the notion that research should treat media features and social practices separately; and the dearth of ethnographic research on Internet news audiences.

The assumption of a division between print, broadcast, and online media has hindered the appraisal of whether Internet news complements or replaces traditional media in audiences' daily budget. With few exceptions (Taneja et al., 2012), most analysts have assumed that consumers devote their attention exclusively to newspapers, television, radio, or the Internet (Gaskins and Jerit, 2012), and have, therefore, failed to register the ways in which news consumers integrate use of different media, by, for instance, searching online for in-depth information about a topic featured in broadcast news, or commenting on a social networking site or on a personal webpage about a newspaper article.

The tendency to focus on either ordinary or extraordinary patterns of phenomena has limited understanding on whether online news audiences are becoming increasingly fragmented or homogenized. While some studies on politically interested information seekers show they tend to seek attitude-reinforcing content (Stroud, 2011), other researchers show that the most accessed online news sites tend to be mainstream news outlets with moderate political views and similar agendas (Hindman, 2009). Boczkowski proposes that while "homogenization might characterize the center of the media spectrum and segmentation its periphery" (2010: 250). He adds that if consumption "was arrayed in a single dimension, the more frequent activities would be located at the center and marked by rising homogenization, and the less frequent ones would be placed at both ends and be signaled by increasing segmentation" (2010: 250).

A third limitation to comprehensive understanding of Internet audiences is the dearth of historical comparisons. For instance, accounts of incidental information acquisition online echo Baum's research on the effects of talk shows on political knowledge and interest of otherwise inattentive audiences. The relationship between online news consumption and information acquisition would greatly benefit from analysis that considered the historical context in which audiences access information, making sense of the continuities and discontinuities (Boczkowski and Lievrouw, 2007) in motivations, behaviors, and interpretations.

Research on Internet news as a resource for civic participation may have also been hampered by a tendency to focus either on media features or on social practices, thus assuming that all news consumption online would either contribute to (Margolis and Resnick, 2000), or have no effect whatsoever on, political engagement (Esser and de Vreese, 2007). Lupia and Philpot contended that the Internet is not a monolith, and urge researchers to focus 'on how certain kinds of web sites affect certain kinds of people' (2005: 1125).

Finally, research on users as news content producers may have suffered from the paucity of ethnographic studies. Most research on citizen journalists and bloggers is based on either surveys or content analysis of their work. The few exceptions to this trend, based on ethnography and in-depth interviews of bloggers and citizens journalists (Anderson, 2010; Robinson and Deshano, 2011) provide a richer understanding of who, under what conditions, and with what consequences engages in news content production outside the realm of professional journalism.

Discussion

These limitations have not precluded previous research from making important contributions about the frequency and mode in which users engage with information online; the kind of news content they seek on the Internet; and the consequences of Internet information consumption for civic knowledge and participation. However, we would like to devote the remainder of this article to propose ways in which future research may overcome these limitations.

The reliance on methodological and theoretical frames inherited from the study of media throughout the better part of the twentieth century may explain, at least partly, the persistence of these limitations. Thus, research tends to be grounded on a unidirectional, one-to-many model of communication, in which there is little room for variance in the content accessed, the times and modes of attention to information, and the impact of news consumption on public life. Moreover, users-as-content producers are mostly examined with respect to their compliance with rules and routines of professional journalists, which may no longer hold true for all professional content producers online.

The online environment allows researchers to challenge traditional assumptions of scholarship on news consumption. For instance, studies of online news consumption could contest the notion that news consumption occurs at designated times and spaces, and instead seek to examine to what extent different users integrate their access to online news with other media use and their daily activities, such as work and commuting. Boczkowski's examination on news consumption at the workplace (2010) shows that access to online news is tied to the flow of the working day and serves as social currency among colleagues. Scholars may also question the stark division between consumption and production, and instead aim at analyzing under which conditions, and with what consequences, news media users engage in information production. Finally, researchers could also challenge the separation between mass and interpersonal communication, as the online environment allows users to access and disseminate information meant both for a mass audience and for a limited network of known acquaintances (such as via email or through social networking sites). This reassessment of the conceptual foundations of scholarship on media would help tackle unresolved dichotomies in the study of online news audiences in particular and in the broader field of media and society in general.

New Media, Political Mobilization, and the Arab Spring

Habibul H Khondker, Zayed University, Abu Dhabi, United Arab Emirates

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article seeks to review the impact of the new media on political mobilization in the Arab Spring of 2011. The article examines the relationship between the information communication technology, especially the new media and its consequences – both intended and unintended – on social movement in the Middle East and North Africa region. Tracing the various arguments in social science literature and taking into account the political developments in the region, the article concludes that on the one hand new media played a critical role in political mobilization culminating in the Arab Spring and on the other hand, the new media can also be used as repressive tools by the authoritarian rulers to their advantage.

Introduction

This article examines the popularity and impact of information communication technology (ICT) on all the spheres of society: the economic, social, and political. ICT was favored by the governments of the Middle East and North Africa (MENA) region, as in other parts of the developing world, as a means for achieving modernization, yet the unintended consequences were more unpredictable and led to political mobilization and played a key role in the Arab Springs of 2011.

The Tunis conference organized by World Summit for Information Society (WSIS) in 2005 was a project of the UNESCO hosted with the support of the Government of Tunisia to promote and institutionalize ICT as it was the mantra of the time to pave the way of a digital revolution. As the world was caught up with the new paradigm of the information society or knowledge-based economy, many developing countries too joined the caravan of information highway. In response to Tunisia's request, the United Nations General Assembly approved the creation of WSIS in late 2001. The WSIS Tunis Commitment recognized that "freedom of expression and the free-flow of information, ideas and knowledge are essential for the Information Society and beneficial for development" (UNESCO, n.d.).

Apart from highlighting freedom of expression as a "key component for the establishment of democratic processes" (UNESCO, n.d.), UNESCO's role was consistent with its promotion of continuing development of the Internet as a global public resource with open access to everyone. Little did the leadership of Tunisia envisage that by 2010, the new information technology would – in addition to playing a role in the creation of an information society and knowledge economy – contribute to the democratic opening of the society by removing authoritarian leaders.

Information Communication Technology and Development

Starting in the last decade of the twentieth century and reaching its peak in the early decade of the twenty-first century, information society, knowledge-based economy, knowledge society, and so on became the new mantra of development. The new development paradigm swept the world, and many leaders of developing countries embraced the ICT to hasten economic development.

Social scientists by and large expressed some sense of skepticism viewing the new technology with its penetrating reach, an invasion into the privacy. Some writers raised the fear of a surveillance society in the offing. Information technology, many thought, would grant government more control. Such fears have been rekindled with the popularization of "Big Data" projects. Some writers, however, saw a great deal of potential in opening up space for free, uncoerced discussions furthering the processes of democratization.

Social science research on the potential of the new media in shaping society began in earnest since Manuel Castells groundbreaking work, *The Rise of the Network Society* (1996) and more recently, *The Communication Power* (2009). A number of writers in the last decade of the twentieth century recognized the potential of Internet as a vehicle for disseminating democracy (Poster, 1995). More recent writers have identified the nuances as well as limits to the role of the new media in politics (Howard, 2011). The discussions on this subject are divided between those who emphasized the controlling role of the new media, a new tool of repression in the arsenal of the dictators and those who see it as tools for democratic openness. Even in democratic societies, the new technology, as some writers point out, pose a grave threat to the freedom and privacy of citizens. One writer traced the evolution of technology from the industrial revolution to the microchip revolution arguing that technology has historically increased control in society and the new microchip would not be an exception (Beniger, 1989). Other writers often get somewhat carried away with the potential role of the new media in shaping politics, opening up a new public sphere, especially in societies where a real public sphere is absent. There are however some writers who have presented a more balanced view on the pitfalls and potential, controlling as well as emancipatory role of the new media.

Academic discussion of the potential of Internet in opening up political space for democratization preceded the 'Arab Spring.' Studies were conducted elsewhere to examine the potential of Internet (Ho et al., 2002; Kalathil and Boas, 2003). The Berkman Center for Internet and Society at Harvard University published a study on Arabic blogosphere in June 2009 where it analyzed 35 000 blogs and systematically mapped the discussions around certain nodes covering such topics

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64135-1

as terrorism, human rights, minority issues, critique of USA, personal issues, and so on.

Their findings dispelled "two common threads of speculation about the role of the Internet in the Arab world. The first is a view of the Internet as primarily a vehicle for radicalization. We found very little support for terrorism or violent jihad in the Arabic blogosphere and quite a lot of criticism …. The second thread is the hope that the Internet will empower political movements that can move Arab societies toward democratic values and governance. This study supports some aspects of the view that the Internet can empower political movements in the region, since it provides an infrastructure for expressing minority points of view, breaking gatekeeper monopolies on public voice, lowering barriers to political mobilization (even if symbolic), and building capacity for bottom-up contributions to the public agenda. But we caution against the idea that these functionally 'democratic' characteristics necessarily travel in the company of classically liberal, historically Western, values regarding individual liberties, freedom of belief and expression, and, ultimately, secular foundations of political rights. The Internet lays a good foundation for a battle of ideas, but it does not necessarily favor a winner" (Etling et al., 2009: 10).

With hindsight, their second point touches the nub as the diverse developments in the postrevolutionary Tunisia and Egypt reveal: the former heading for a tolerant democracy, while the later portends a less-tolerant authoritarian rule. Political mobilization in the latter case seems to be top down.

ICT and the Arab World in Perspective

Since the 1990s Internet has revolutionized the world. The drift of this revolution reached the Middle East at the beginning of the twenty-first century. The rapid spread of Internet technology in the region was part of its high-paced economic transformation and was effectively pushed by the respective governments. Countries with new wealth sought to achieve modernization and bought into the paradigms of technology-driven development models. Especially the Gulf countries took the lead in the economic growth with the help of the wealth generated from the export of hydrocarbon and rapid building of infrastructure; developments of ICT were not lagging behind. Yet, those who share a technological deterministic explanation of social uprising fail to recognize that the countries with the highest penetration of ICT were not at the forefront of what has come to be known as the 'Arab Spring.'

It would be useful to remember that political protests and upsurge began in the MENA region following the controversial presidential elections of 2009 in Iran, which returned President Ahmedinajad to a second term. The elections were charged with widespread irregularities, and accusations of rigging were numerous. The so-called Green Revolution, since the protestors, who wore green failed in Iran but triggered a series of uprisings in the entire region that came to be known as the 'Arab springs.'

The Middle East as a region has a population of 231 million of which 90 million as of December 2012 are Internet users. If we look at the world, of course in terms of aggregate number of people using Internet we find that the largest users of the Internet are countries like the population giants such as China, India, Brazil, Indonesia, and Nigeria. However, when we look at the Internet penetration as percentage of the population, Europe and North America are the world leaders with the exception of South Korea.

Table 1 Internet penetration in the Arab world vis-à-vis leading countries of the world in 2014

Country	*Internet users (in millions)*	*Population (in millions)*	*% of Internet users*
China	641.6	1300	46.03
USA	279.8	322	86.75
India	243.1	1200	19.19
Japan	109.2	126	86.03
Brazil	107.8	202	53.37
Russia	84.4	142.4	59.27
Germany	71.1	82.6	86.78
Nigeria	67.1	178.5	37.59
UK	57.0	63.4	89.90
France	55.4	64.6	85.75
South Korea	45.3	49.5	91.52
Egypt	40.3	83.3	48.34
Iran	22.2	78.4	28.29
Morocco	20.2	33.4	60.33
Saudi Arabia	17.3	29.3	59.24
UAE	8.8	9.4	93.24
Algeria	6.6	39.9	16.70
Israel	5.9	7.8	75.80
Syria	5.8	21.9	26.66
Tunisia	5.0	11.11	45.46
Yemen	4.7	24.9	19.14
Jordan	3.3	7.5	44.98
Lebanon	3.3	4.9	67.19
Kuwait	3.0	3.4	86.86
Iraq	2.7	34.7	7.79
Oman	2.5	3.8	65.82
Qatar	2.1	2.2	96.65
Libya	1.3	6.2	21.79
Bahrain	1.29	1.34	96.53

Source: http://www.internetlivestats.com/internet-users-by-country/.

Given its sheer population size, China is a world leader in the use of Internet. As of 2014, China has 641 601 070 Internet users of its 1.3 billion population, which accounts for 46.03% penetration accounting for 21.9% of the Internet users of the world with 19.24% of the world share of population. However, in terms of penetration of Internet vis-à-vis the population, only four countries of the world have over 90% Internet penetration. Of the four countries, three are in the Gulf region of the Middle East. They are Qatar (96.65%), Bahrain (96.53), and UAE (93.24). South Korea has an Internet penetration rate of 91.52% (Table 1).

There are over 128 million Internet users and around 82 million users of social media in the Arab world as of 2014, which stands 22% of the population, and with around 41% Internet penetration rate and a whopping 110% mobile telephony penetration this region is ahead of other developing regions of the world. Within the region, the penetration rates vary nationally. For example, Qatar ranks number 1 in the use of Facebook followed closely by the UUAE social media.

According to the Arab Social Media Report of 2014,

> social media has been growing rapidly in the Arab World since 2011 and has continued to do so over the past year. Globally, Facebook boasted 1.28 billion monthly active users (MAUs) by the end of the first quarter of 2014, including companies, brands, and governments, with 1.01 billion of Facebook's monthly active users accessing it through smart mobile devices. Twitter has also seen similar strong growth globally, with 255 million monthly active users as of end of 1st quarter of 2014, with 198 million of them accessing the platform through mobile devices. LinkedIn, too, has seen healthy growth in users this year. As of January, LinkedIn had over 300 million members, with 39 million of them being students and college graduates.

> With these global highlights in mind, growth of social media usage in the Arab world has been equally strong, with the number of users increasing by 49% on Facebook, 54% on Twitter and 79% on LinkedIn since May 2013. (p. 6)

Compared to other prominent developing regions, the Internet penetration in the MENA is quite remarkable. For example, in India more people have access to mobile phone than to toilets. Just over half of India's population uses cell phones, yet only 13% of Indians use the Internet, with only 6% on social networking sites, according to the Pew Research Center. Other BRICS countries – Brazil, Russia, India, China, and South Africa – average 46.5% use, and worldwide, only 36% adults reportedly have access to the Internet (Reilly, 2013).

As social media may have played a role in facilitating social mobilization and social movement in some of the countries in the region, social movement or as in some cases it is called the 'Arab Spring' has also played a role in popularizing the Facebook as a social media in the region. The speed of penetration between 2011 and 2012, as **Table 2** shows, was nothing but spectacular in Jordan, Kuwait, and Tunisia.

Table 2 Facebook penetration in the MENA region

Country	*2010 (December)*	*2012 (June)*	*2014 (May)*
UAE	45.38	40.6	58.0
Israel	42.93	45.3	50.2[a]
Qatar	33.95	29.3	60.9
Bahrain	34.27	25.9	38.9
Lebanon	23.11	32.7	45.9
Kuwait	20.64	34.3	48.3
Tunisia	17.55	27.9	42.1
Jordan	17.06	34.1	47.9
Saudi Arabia	12.24	19.2	28.1
Palestine	10.76	21.2	31.4

[a]In December 2012.

The Arab Spring and Social Media

There is an inherent contradiction in the spread of information revolution since it is often the government, aided by corporate interests, that promotes the new media thus inadvertently creating a space for civic activism. As Roland Robertson argues in another context, the growing surveillance technology – an aspect of new, invasive information technology – threatens an open society leading to a syndrome of open society and closed mind (Robertson, 2007). Drawing on his metaphor, it can be said that in other contexts, it may create a tension between closed society and open mind. New information technology has clearly the transformative potential to open up spaces of freedom. The recent political transformations in the MENA region provide us an opportunity to examine both the limits and potential contributions of the new media in paving the way for freedom and openness.

The Arab Spring of 2011–12 brought to public attention the role of the social media in political mobilization and social movement in the Arab World. As long-standing authoritarian regimes in Tunisia and Egypt fell in the face of social uprisings, several commentators sought to analyze the role of the ICT in whipping up a veritable revolution pushing long-standing dictators out of office. Some commentators likened the new media as responsible for creating a virtual civil society while the real or off-line civil society was either nonexistent or anodyne at best.

Is Internet or Facebook, or Tweeter or their combined effect good enough to cause social revolution leading to freedom? What about the use of the same instruments of the new media by the political power as tools of repression? What are the ancillary factors that may come into tilting the contest one way or the other? Writers such as Rasha Abdulla (2011) and Eltantawy and Wiest (2011) argue that Facebook and Twitter were instrumental in both organizing and motivating social movements in the Middle East. Others favor a more integrated view in explaining the Arab Spring where new media and traditional media, that is, television and newspapers complemented each other (Khondker, 2011).

Tunisia

The Arab Spring began in Tunisia and then affected Egypt. This genealogy can be improved by adding the early, albeit much smaller-scale, ICT-mediated movements in Egypt since 2005, and the Iranian protests and social movement, known as green movement that rose and failed, yet was successful to draw international attention and support, modify the local political scene and possibly sent a message that the idea of a social movement is not off the agenda in the Gulf countries.

Tufekci and Wilson (2012) remind us: "From about 2005 on, there were persistent efforts by small but dedicated groups, starting with the Kefaya ("Enough") movement and later the April 6th Youth Coalition. The unrest was not, by any means, limited to the online sphere. Indeed, the April 6th movement was initially formed to support a labor strike. However, social media and satellite TV were the main public spaces where politically sensitive subjects were openly discussed and dissent could be expressed. The introduction of Facebook in Arabic in

2009 amplified this process. Political content online increased, with multiple campaigns by citizen journalists and online activists exposing poverty, corruption, and human rights abuses, including torture. However, until the Tunisian uprising, physical protests in Egypt remained fairly small and the regime appeared to be firmly in control" (Tufekci and Wilson, 2012: 364).

Why the 'Arab Spring' revolutions did not sweep the entire Gulf region felling all the authoritarian regimes paving the way of democracy across the region will be debated for some time. Failed or successful are the call of the historians for which some time has to be elapsed; however, what is clear from the uprisings in the region, is that information technology has been a crucial accessory in the opening up of the MENA region.

The authoritarian political regimes, ironically, brought the new information technology in their respective countries as a means for advancing or sustaining economic growth. It is the compulsion of modernization and keeping up with the rest of the economically (and thus technologically) advanced societies that made the political leaders to facilitate and implement the infrastructures of the advanced new technology that was meant to connect these societies to the global village. Little did the leaders know that technology, especially, the Internet technology is a double-edged sword. While it played a positive role in upgrading their economic systems, there were unintended consequences of the ICT, one of which was impact of the technology on the political processes.

In a study following the Egyptian social uprising that had Tahrir Square as the fulcrum of the movement it was found that the average age of the participants was 28.5 years with an average education of 5.3 years of schooling. More importantly, 80% of them had Internet access at home and 52% of them had mobile phone with Internet connectivity (Tufekci and Wilson, 2012: 369). Lest, this might give an impression that it was a movement of the techies, it was also interesting to observe that 34% of the respondents had previously attended political rallies (Tufekci and Wilson, 2012: 369).

The above-mentioned study shows that a combination of various factors, that is, presence of a revolutionary crisis, an aging authoritarian leader, a determined public spearheaded by an educated, technology savvy middle-class protestors, and the revolution became an inevitability. The introduction of Facebook in Arabic had a direct and penetrating impact as it indigenized Facebook to local population, taking it beyond the urban elite.

Many writers, however, fall in the trap of technological determinism giving excessive weightage to the forces of Internet and mobile technology as the causes of the Arab revolutions. All revolutions cannot be reduced to a singular cause. There are always multiple factors causing social revolutions.

Technology, whether it is old media or new media, plays a complementary role.

In the Arab Spring the new and the old media joined forces to unleash the revolutionary potential (Khondker, 2011).

In Tunisia, when the fruit-seller, Mohammed Bouaziz resorted to self-immolation to protest the price hike and political repression, the event became national and eventually international news thanks to the combined effects of conventional media and the new media. Both television networks (such as Al Jazeera) and Facebook played a significant role in disseminating information and mobilizing the masses of protestors in Tunisia. Both virtual and real revolutionaries came out in droves to protest.

Mr. Khaled Koubaa, the president of Internet Society in Tunisia reported that of the 2000 registered Twitters hardly 200 were active users but before the revolution there were two million users of Facebook. "Social media was absolutely crucial," says Koubaa. "Three months before Mohammed Bouazizi burned himself in Sidi Bouzid we had a similar case in Monastir. But no one knew about it because it was not filmed. What made a difference this time is that the images of Bouaziz were put on Facebook and everyone saw it." (Beaumont, 2011). Stressing the role of the new media, Zeynep Tufekci (2011) makes the point that in Tunisia protest movements in 2008 were crushed without significant backlash effects. Part of the reason was that at that time there were only 28 000 Facebook users in Tunisia. In other words, the new media penetration was low. In December 2010 the news of self-immolation of Bouazizi in a small town was transmitted by the new media triggering mass protests.

In 2010 at the onset of Tunisian revolution to oust Ben Ali, the government was not caught in surprise. It was doing all it could to subvert the movement by shutting down or hacking websites, and so on. Ammar was in the process of stealing an entire country's worth of passwords. Ammar is known as the Internet censorship in Tunisia which did all it could do to disrupt Internet, the very tool that people are using for their activism becomes the very means by which their identities could be compromised (Madrigall, 2011).

The Tunisian revolution spilled over into Egypt. In both cases, the new media played a key role. The revolution was labeled as Jasmine revolution in part because it was not as violent as it could have been – as it unfolded in Libya months later. Given the dominant role of the new media, Tunisian and Egyptian revolutions are called Facebook or Twitter revolutions. There is no question that the social networking applications played a vital role in organizing and publicizing social protests.

Egypt

On 6 April 2008 when the Egyptian authority locked up Kareem Al Beheiri, a worker-turned labor rights activist and a blogger for allegedly instigating riots, the news was picked up by the conventional media but did not either hog the headlines or stay in the media limelight for long. The news of his protest was subsumed under the broader protests and demonstrations against the rising food inflation in Egypt and a number of other developing countries. Beheiri was tortured in custody and later released. His cyber-activism was part of a growing movement, albeit gradual, where new media was used effectively to mobilize people against a regime in power for three decades. Cybe-ractivism in Egypt had emerged since 2004 as it began to spread in other parts of the Middle East, marking the ushering of cyber-civil society, and a virtual replacement for the muzzled media. Since 2008, in the face of a global economic crisis and enhanced political repression, Egypt has seen growing protests where various means of new media have played a crucial role. How significant is the role is, however, a matter of some

contention. When Wael Ghonim, a Google Marketing executive and a key cyber-activist in Egypt, stated in an interview with CNN days before the ouster of Hosni Mubarak, "If you want to free a society just given them internet access" (Khamis and Vaughn, 2011: 1) he was probably exaggerating. Shortly after the stepping down of President Mubarak, in an interview with CNN, Ghonim said:

"I want to meet Mark Zuckerberg 1 day and thank him [...] I'm talking on behalf of Egypt. [...]. This revolution started online. This revolution started on Facebook. This revolution started [...] in June 2010 when hundreds of thousands of Egyptians started collaborating content. We would post a video on Facebook that would be shared by 60 000 people on their walls within a few hours. I've always said that if you want to liberate a society just give them the Internet. [...] (Huffington Post, 11 February 2011).

Gamal Ibrahim, a young parent named his daughter "Facebook" in recognition of the role of the social media played in bringing about the revolution (CNN, 2011). The exuberance is understandable given the timing of the birth of the baby girl. But it was at best an example of exuberance.

The Egyptian revolution was well organized, coordinated and civil (Abaza, 2011; Bamyeh, 2011) and in every step, the new media played its part. On 6 June 2010 Khaled Said, an Egyptian blogger was dragged out of a cybercafé and beaten to death by policemen in Alexandria, Egypt. The café owner, Mr. Hassan Mosbah, gave the details of this murder in a filmed interview which was posted online and pictures of Mr. Said's shattered face appeared on social networking sites. On 14 June 2010 Issandr El Amrani posted the details on blog site Global Voices Advocacy (*Global Voices Advocacy*, accessed on 24 June 2011). A young Google executive Wael Ghonim created a Facebook page "We Are All Khaled Said" that enlisted 350 000 members before 14 January 2011 (Giglio, 2011: 15).

Digital media in Egypt was used to tell the stories of police brutality, violence, and blatant injustice. In the end the new media helped protestors mobilize specific political outcome such as the removal of President Hosni Mubarak.

Control of conventional media made the role of new media more relevant. During the anti-Mubarak protests, an Egyptian activist put it succinctly in a tweeter message: "we use Facebook to schedule the protests, Twitter to coordinate, and YouTube to tell the world" (Global Voice Advocacy, 2010). However, to overstate the role of the new media may not be helpful. Surely, social network sites and Internet were useful tools, but conventional media played a crucial role in presenting the uprisings to the larger global community who in turn supported the transformations.

Saudi Arabia

On 17 June 2011 when Maha al-Qahtani, a 39-year-old Saudi woman decided to drive a car in Riyadh, a conservative city with her husband on the passenger seat, she was arrested and later released. However, her defiant protest received wider media attention and got traction in the new media. Ms. Manal al-Sharif, a 32-year-old IT consultant who set up a Facebook campaign called women2drive was arrested on May 21 (Allam, 2011). Her Facebook site remains a space for cyber-activism. A woman posted a picture of a woman driving wearing an *abaya* (a black dress covering the entire body) on this site which now carries the name of Manal and Bertha. More and more women and men – Saudis and non-Saudis – continue to express solidarity posting various contents one of which includes a message of support for the freedom–loving Saudi women from the US Secretary of State, Ms. Hillary Clinton. The Facebook site has also hosted a YouTube video clipping made from a television coverage of an earlier protest of similar nature when 47 Saudi women of cross-sections broke the taboo by driving their cars in defiance of government ban on 6 November 1990. New comments and contents taken from televised news are being added to the women2drive site almost on a daily basis.

Whether these gestures mark the new beginning or not is a moot question. The incipient cyber-activism in Saudi Arabia may not herald an Arab Spring, at least, in the near future. The outcomes of the spread of the new media are likely to remain uneven in different parts of the MENA region. Despite the uneven outcomes, there seems to be no holding back of the marches of cyber-activism in this region. Cyber-activism has been defined as "the act of using the internet to advance a political cause that is difficult to advance offline" (Howard, 2011: 145).

As the cyber-protests signify a window of change in Saudi society thanks to the new media – assorted tools such as Facebook, Twitter, and Internet-based communication – there are sites hosted by conservatives who call these women names, create their own websites thus compete for capturing space in the new media. It is impossible not to pay attention to two points. First, the new media is a tool, a means for and not the ends of social movement. Hence, the role of new media is contingent on the movements on the street. And the new media has been a contesting site of resistance for all the interest groups in the twenty-first century (Ho et al., 2002). The debate over the competing role of the conventional media versus new media has been a false debate. Even before the uprisings in the MENA region, it was argued that "horizontal networks of communication, such as the Internet, to have significant impact on the majority of the population they need to be relayed by the mass media, as was the case in the diffusion of the pictures of torture in the Abu Ghraib" (Arsenault and Castells, 2006: 303).

There is no question that social media played a significant role in the political movements in Tunisia and Egypt but one should not overstate the role. Conventional media, especially television medium such as Al Jazeera's role was crucial. However, the most important underlying factor was the presence of revolutionary conditions and the inability of the state apparatus to contain the revolutionary upsurge. In this schema, social media was a vital tool – a necessary condition – especially in the face of a muzzled conventional local media but a tool nevertheless. It was not a sufficient condition. Stressing the role of Al Jazeera in Arabic as well as the BBC, France 24, Al Hiwar, and other channels in presenting the news of the Arab Spring, Manuel Castells states, "Al Jazeera has collected the information disseminated on the Internet by the people using them as sources and organized groups on Facebook, then retransmitting free news on mobile phones. Thus was born a new system of mass communication built like a mix between an interactive television, internet, radio and

mobile communication systems. The communication of the future is already used by the revolutions of the present. [emphasis in the original]."

Castells continues: "Obviously communication technologies did not give birth to the insurgency. The rebellion was born from the poverty and social exclusion that afflict much of the population in this fake democracy, …" (Castells interview posted on http://globalsociology.com/2011/02/07/the-sociology-elders-on-the-social-movements-in-tunisia-and-egypt/)

The new media's role can be likened with the historic role of print media in fostering nationalism through what Benedict Anderson (1991) calls 'print capitalism,' or the role of literacy in raising consciousness in the prerevolutionary eighteenth century France as the works of Robert Darnton (1982) and John Markoff (1986) illustrate. Markoff shows that in regions with higher literacy, revolutionary activities were more organized compared to those in low literacy regions. However, revolution did not wait for the even spread of literacy.

Social network or not, Tunisia, Egypt, Libya, Syria, Yemen, and Bahrain were ready for revolutionary movements due to an assortment of politico-economic conditions. Similarly, to what extent these revolutions will be successful or not depends on several factors – some known and some yet unknown, in which the social network may play a supportive role at best.

Like the 'revolution,' the discussion on social or new media or the role of ICT, generated more heat than the light. The revolution itself was not revolutionary in some cases as it replaced one military dictator with another with some diversionary electoral exercises to purchase some kind of short-lived political legitimacy. At least, that was the fate of the largest of the 'Arab Spring' countries, namely, Egypt. Ignoring the details of 2 years of political drama where in a popular vote, the Muslin Brotherhood supported leader, Dr. Mohamed Morsi, a US trained engineer, representing the Muslim Brotherhood was elected president of Egypt in June 2012, and as his regime played roughshod in implementing shariah-compliant laws that upset sections of the Egyptian middle class who were interested in seeing economic reforms rather than imposition of religious values. Many who supported the revolution quickly became disillusioned of Morsi's pro-Islamic regime.

Throughout these processes from the removal of the dictator Hosni Mubarak in January 2011, electing Mohamed Morsi in June 2012, and removing Mr. Morsi in July 2013, social media continued to play a role. And as Mohamed Morsi became president on the back of a new media generated social uprising, he turned against the new media and the bloggers reciprocated by turning against his pro-Muslim Brotherhood regime. A high-profile blogger Ahmed Doume was sentenced to 6 months prison term by Morsi regime. His was one of the two dozen cases of 'insulting the president' in the first 200 days of Morsi rule. Apparently, this was four times of the similar cases in the 30 years of Mubarak rule (VOA, 2013). As the new military leader General Sisi helped himself to the helms of affairs in July 2013 and consolidated his power through a show election in early 2014, which many Egyptians stomached despite its questionable legitimacy, because a large number of Egyptians, barring the Muslim Brotherhood, were so dismayed by the rule of President Morsi. However, Field Marshal Sisi too turned against the freedom of speech and matched the intolerance of the Muslim Brotherhood by his regime's intolerance of Muslim Brotherhood and the free use of media. One of the early casualties of his regime – as far as freedom of expression was concerned – the satirical television show of Dr. Bassem Youssef, the Jon Stewart of Egypt (Hellyer, 2014).

It is possible to see the Egyptian political drama as a fight on or off against the new media. When new media serves political power, it is acceptable and when it does not, it remains an instrument of social disruption and is suppressed. Political authorities by supporting or opposing recognize the potential power of the new media. An analysis of the blogosphere in Egypt and Saudi Arabia in 2013–14 showed a growing blogging fatigue especially of the left and the liberal voices. The Muslim Brotherhood blogs remain visible. There has also been a change of platforms from blogging to Twitters, especially, in Saudi Arabia (Othman, 2014).

Conclusions

From the very onset of the spread of ICT, many saw it as a tool of social and economic progress. Astute social scientists were skeptical seeing the new penetrating technology an invasion of privacy paving the emergence of surveillance society. Information technology, in the hands of the government, can be a source of control, while in the hands of the public it may be a tool for emancipation.

The spread of ICT in the emerging digital revolution, technology unwittingly played a role in Tunisia's democratization, spreading antiauthoritarian movements in Egypt and other MENA countries, which came to be known as the Arab Spring.

While some writers grant social media too much credit, for example, naming Iran's Green Movement the 'Twitter Revolution' and labeling the Arab Spring the 'Facebook Revolution,' others, however, were somewhat cautious and saw social media playing a complimentary role. Social media in tandem with other electronic media supported the social movement and political mobilization on the street, which had a deeper root in the social structures and political developments. Surely, in the political uprisings of 2011–12 new media's role in creating a virtual civil society in the absence of a real or off-line civil society needs to be recognized without falling in the trap of technological determinism. At the same time one has to consider the role of the new media in promoting right-wing movements and forces such as the Islamic State of Iraq and the Levant (ISIL) that threaten democracy and peace. The new media technology is Janus-faced.

New Religious Movements

Eileen Barker, London School of Economics, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'New religious movements' (NRMs) is a term used to describe minority religions that have recently become visible in a society. They have appeared throughout the world and throughout history, and they have differed from each other with respect to their beliefs, practices, and lifestyles, as well as the effects they have on their members and on society. However, they do tend to consist of converts; to have a membership that is atypical of the rest of the population; to have a charismatic leader; to change more rapidly and radically than older, more established religions; and to evoke fear, suspicion, and, not infrequently, antagonism from nonmembers.

Definitions

The concepts of 'newly arising religion,' then 'new religion,' entered Japanese vocabulary after the Second World War when restrictions imposed on religions other than state Shinto were lifted (Shimazono, 2004; Mullins et al., 1993). Around the late 1960s, Western scholars began to use the term 'new religious movement' (NRM) to describe (1) religions that were new to the West, although, like some forms of Tibetan Buddhism, they could have existed for hundreds of years in another part of the world; and (2) minority religious organizations and spiritual communities that might be referred to as a 'cult' or 'sect,' in order to distinguish them from a 'church' or 'denomination.' However, as the terms 'cult' and 'sect' were increasingly used in popular parlance to denote a negative evaluation, Western scholars had adopted the term NRM in an attempt to distance themselves from the blanket condemnations associated a priori with these labels and to present their analyses from a more objective perspective. This move led to accusations from sections of the media and anticultists (discussed in this article) that the scholars' use of the concept was an insult to 'genuine religion' and little more than an attempt to whitewash the movements – accusations that, by the turn of the twenty-first century, had resulted in some scholars and the movements themselves preferring to use terms such as 'alternative religions' or 'minority religions.'

There are, however, several other problems related to the term NRM. First, it has not been used to refer to all new religious groups (e.g., the United Reformed Church would not be called an NRM, although it came into being only in 1972 as the result of a merger between English Presbyterians and Congregationalists). Second, some groups classified as NRMs protest that they are not new but can claim a heritage of hundreds of years; the International Society for Krishna Consciousness (ISKCON) traces its lineage through the sixteenth-century monk Chaitanya Mahaprabhu. Interestingly, in Japan, movements such as Mahikari, Shinreikyō, and Agonshū that have appeared since 1970 are now referred to as 'new new religions' (*shinshinshūkyō*); indeed, some Japanese scholars are now calling movements that have emerged in the twenty-first century 'new new new religions.'

Third, several groups deny that they are religions, many preferring to classify themselves as spiritual, philosophical, or educational; and some, such as the Raelians, are avowedly atheistic. NRMs are, however, frequently defined rather loosely as new insofar as they have become visible in their present form since World War II, and religious insofar as they address at least some of the questions of ultimate concern that traditionally have been addressed by more established religions – questions such as 'What is the meaning of life?', 'Is there life after death?', and 'Is there a God?'.

Another way of defining a new religion is as a group or movement that consists predominantly of a first-generation membership. This has the advantage of allowing one to identify a relatively recognizable group that may share certain characteristics with other first-generation movements. It also helps to alert us to the fact that NRMs can change rapidly within a generation (discussed further in this article). There can, however, be difficulties when deciding how to classify movements that have existed for decades or even centuries as proselytizing movements; for example, 70% of the worldwide membership of the Church of Jesus Christ of Latter-day Saints (popularly known as the Mormon Church) are converts, although the Church itself has been around for nearly 200 years.

Numbers

The total number of NRMs is unknown and will, of course, differ according to the precise definition that is used. In the West, there are around 1500 groups, and more if all the 'self-religions' – that is, religious movements that (also) aim at self-improvement – are included (*see* Religiosity: Modern). Several thousand more may be found in Latin America, in the former Soviet Union, and throughout Asia, including the Indian subcontinent. It has been estimated that over 10 000 new religions are to be found in Africa, although many of these are referred to more frequently as African Independent Churches.

The number of members is even more difficult to assess, and estimates can vary by millions. Among the relatively few large international movements: in 2011, Sōka Gakkai was claiming around 12 million members worldwide; between 8 and 14 million persons are said to have taken one or more of the courses offered by Dianetics or the Church of

Scientology, but the vast majority of these people will no longer consider themselves to be Scientologists; it has been claimed that 6 million people have been trained as Transcendental Meditators; and Cao Đài also claims 6 million members, most of whom are ethnic Vietnamese. If nineteenth-century sects are defined as new religions, several of these have tens of thousands of members or more worldwide: Seventh-day Adventists claim over 15 million worldwide; Mormons claim over 14 million; Jehovah's Witnesses claim 7.5 million; the Salvation Army just over 1.5 million; and the Christian Community, popularly referred to as the 'Exclusive Brethren,' is thought to have around 43 000 members worldwide. There are, however, probably no more than a few hundred NRMs that have emerged in the West since the 1950s that have more than 1000 adherents; the majority are small, local groups with no more than 100 or so followers at any one time.

The difficulty of obtaining accurate figures is confounded by the fact that most movements have several levels of membership, ranging from the fully committed, who may live with and work for their movement, to 'sympathizers' who might belong to more than one group (especially within the New Age or Human Potential movements). Furthermore, both the NRMs and their opponents tend to exaggerate membership figures, the former because they wish to be seen as more successful than they really are. Opponents of NRMs often want to exaggerate the threat that the movements pose, and many opponents adhere to a brainwashing thesis (which claims members are recruited using irresistible and irreversible mind-control techniques), which leads them to ignore or deny the fact that large numbers of converts leave after a short period of membership (Barker, 1989).

Variety

Perhaps the most important generalization to be made about NRMs is that they are quite diverse. There have, of course, been new religions throughout history; early Buddhism, early Christianity, early Islam, and early Methodism were NRMs. But while most of the movements that arose in previous times were offshoots of the prevailing traditions in their society of origin, the range of traditions, permutations, and combinations to be found within the current wave of NRMs is without precedence. This may in part be explained by dramatically increased social and geographical mobility, the phenomenal expansion of the mass media, and various other processes subsumed under the rubric of postindustrial globalization. Thus, for example, one can find people brought up in the Judeo-Christian tradition deciding to join the Brahma Kumaris, Nichiren Shoshu, Mahikari, Falun Gong, or Hizb ut-Tahrir – NRMs drawn, respectively, from the Hindu, Buddhist, Shinto, Qi Gong, and Islamic traditions. There are, moreover, NRMs that have derived their inspiration from the beliefs and practices of Wicca, Paganism, Occultism, and Esotericism; others have turned to modern philosophies and ideologies, psychological and psychoanalytic theories, astrology, and, indeed, a variety of secularisms. Yet others, such as the Unarius Academy of Science, the Raelians, the Aetherius Society, and the Church of Scientology, owe much to ideas found in works of science fiction; and there are those that would seem to defy membership with any kind of tradition, or to be composed of a thoroughly syncretistic bricolage of traditions and innovative notions, two very different but colorful examples being L'Aumisme Religion Universelle de l'Unité des Visages de Dieu (also known as Mandarom) and the Nuwaubians (also known as the Holy Tabernacle Ministries) (Barker, 1989; Dawson, 1996; Melton, 1992; Miller, 1995). Finally, it should be added that there are now growing numbers of virtual new religions that exist purely or mainly on the Web (the Church of the Flying Spaghetti Monster with its membership of Pastafarians is an oft-cited example) and a series of movements that have been referred to as 'invented religions' or 'hyperreligions,' which include movements that have developed out of various forms of popular fiction, examples being Discordianism, The Church of All Worlds, Jediism, and Matrixism (Possamai, 2012).

Many of the better known NRMs (such as the Children of God/The Family International, the Church of Scientology, the Twelve Tribes, The Way, and the Church Universal and Triumphant) originated in the United States. Other movements developed in various parts of Western Europe (e.g., The Emin, Exegesis, Findhorn, and the Jesus Army in England; Damanhur in Italy; Smith's Friends in Norway; the Revelation of Arès in France; the Lou Movement in the Netherlands; and the Antoinistes in Belgium); and, particularly after the fall of the Berlin Wall in 1989, several emerged in Eastern Europe and the former Soviet Union (e.g., Vissarion's Church of the Last Testament in Siberia, the New Jerusalem in Romania, and Mariya Devi Khristos's White Brotherhood in Ukraine). Moreover, a large number of movements that are now familiar throughout the world originated in the Indian subcontinent (e.g., ISKCON, Sai Baba, the Rajneeshee/Osho sannyasins, the Brahma Kumaris, and Ananda Marga).

African new religions that have hit the headlines include the Lord's Resistance Army and the Movement for the Restoration of the Ten Commandments of God, but there are thousands of others, particularly in Sub-Saharan Africa, many of which, such as Cherubim and Seraphim as well as the Embassy of the Blessed Kingdom of God for all Nations, have migrated to the West and other continents around the world (Adogame et al., 2012; Clarke, 1998). The Rastafari movement arose in Jamaica, worshipping the emperor of Ethiopia, Haile Selassie. Latin American NRMs include various varieties of Candomblé and the Universal Church of the Kingdom of God from Brazil and Santa Muerte from Mexico (Torre Castellanos, 2012). From Indonesia, we have SUBUD; from Malaysia, there is the Sky Kingdom sect, sometimes known as the Teapot Cult because it built a giant teapot to symbolize its belief in the purity of water. Vietnam gave rise to Cao Đài, Australia to the Jesus Christians and the Magnificat Meal Movement, and New Zealand to Centrepoint.

As already intimated, Japan has been home to hundreds of movements, including Sōka Gakkai, Shinnyoen, Tenrikyo, Sūkyō Mahikari, Risshō Kōsei-kai, and the infamous Aum Shinrikyo, which now operates under the name of Aleph (Shimazono, 2004). The third most popular faith in Taiwan (after Buddhism and Taoism) is I-Kuan Tao (Yõguàn Dào or simply IKT), which originated in twentieth-century mainland

China, where it was outlawed (Lu, 2008). Other important Taiwanese NRMs include the True Buddha School and the Tzu Chi Foundation, known for its charitable work throughout the world. Throughout its history, mainland China has also spawned new religions of various forms, commonly derived from Confucianism; Taoism; Buddhism; Chinese 'folk religions'; and, more recently, the 'Qigong Fever' (Palmer, 2007). Following the partial relaxation of religious persecution in the People's Republic of China after the 'Cultural Revolution,' there has been a dramatic growth in unregistered religions that meet illegally for worship. So long as they are not seen as a threat by the state, these might be allowed to exist, but they are always in danger of being officially condemned as an 'evil cult,' with their members facing imprisonment and/or, most notably in the case of Falun Gong, 'reeducation.'

Numerous new religions have emerged from the Islamic traditions of various countries: the Nation of Islam began in the United States, Hitzb ut-Tahrir was founded by a Palestinian in Israel, the now-banned Al-Muhajiroun emerged in the United Kingdom, Tablighi Jamaat came out of India, the Gülen movement originated in Turkey, and the People's Mujahedin of Iran (MEK) operated out of Iraq. Some movements that are referred to as NRMs remain within the folds of their religious traditions. Thus, while the Apostles of Infinite Love and House of Prayer are rejected by the Vatican, Communione e Liberazione, Fokolare, the Neocatechumenal Way, and Opus Dei are accepted as part of the Church.

Some NRMs, such as the Unification Church, have relatively elaborate and systematic theologies; others consist of what might appear to be a jumble of uncoordinated pronouncements. Practices include chanting, meditation, ritual magic, dance, formal liturgy, and group therapy. Some members of NRMs live independently in high-rise apartments; others live together in rural communes (Miller, 1995). Lifestyles may be ascetic or hedonistic. Attitudes toward women, children, and the outside world vary. Some groups, such as the Rajneeshee movement, have indulged in promiscuity and sexual orgies; others, such as the Brahma Kumaris, practice celibacy. Some movements are rich; others are poor; sometimes the leaders become rich while the grassroots members become poor. The movement's organization may be democratic or authoritarian. The leader may be seen as a guru, teacher, prophet, messiah, or god. He (or sometimes she) might, like Sai Baba, perform miracles; or might, like Sun Myung Moon, claim to receive revelations directly from God – or, like Osho, claim to be a god. Alternatively, the leader might, like JZ Knight and Elizabeth Clare Prophet, channel messages from Ascended Masters, or, like Ruth Norman, Raël, and George King, they might be in touch with aliens from another planet. Some NRMs are destructive, and others benign. Most, like older, more traditional religions, can have positive effects some of the time for some of their members and negative effects at other times for other members.

Attempts to classify NRMs have been largely unsuccessful, the sheer variety having made well-nigh impossible any elegant typologies such as those that Ernst Troeltsch, Milton Yinger, and, perhaps most famously, Bryan Wilson (1970) elaborated for the largely Western, Christian-based sects of the nineteenth century. Possibly the most widely adopted attempt has been Roy Wallis's (1984) distinction between 'world-rejecting,' 'world-affirming,' and 'world-accommodating' movements.

Characteristics

Despite the enormous variety, there are, nevertheless, certain characteristics that are commonly found among NRMs merely because they are both new and religious. First, new religions, insofar as they are composed of first-generation members, are likely to display singular enthusiasms, because converts to any religion tend to be more zealous than those born into their religion. Second, the membership is usually atypical of the general population; for example, although in the past NRMs frequently appealed to the socially and/or economically oppressed, the NRMs that became visible in the West in the 1970s appealed disproportionately to young adults from middle-class backgrounds. The movements had, thus, a zealous, healthy, well-educated, but inexperienced membership with few dependents or responsibilities. Third, founders of new religions are frequently accorded a charismatic authority by their followers and are, thus, relatively unconstrained by rules or tradition and, consequently, both unpredictable and unaccountable to anyone.

Fourth, NRMs often embrace dichotomous worldviews that permit little qualification. The world is divided unambiguously into 'them' versus 'us' people, 'true' versus 'false' beliefs, and 'good' and 'godly' versus 'evil' and 'satanic' morals and practices, and time is split between 'before' versus 'after' significant events such as conversion or the coming apocalypse. Fifth, NRMs, given that they present an alternative to the status quo, are commonly regarded with suspicion and/or antagonism by the host society. Understandably, these fears have been reinforced by horrific incidents such as the mass suicides and murders associated with the People's Temple (Guyana, 1978), the Branch Davidians (Waco, TX, 1993), the Solar Temple (Quebec, Switzerland, and France, 1994–95), Aum Shinrikyo (Tokyo, 1995), Heaven's Gate (San Diego, CA, 1997), the Movement for the Restoration of the Ten Commandments of God (Uganda, 2000), and Al Qaeda (in the 9/11 attacks, New York and Washington, DC, 2001).

Changes

A sixth characteristic of NRMs is that they are likely to change far more rapidly and radically than older, more established religions. Taking demographic factors alone: youthful converts get older, and the arrival of a second generation will mean not only that resources such as time and money have to be devoted to their care and socialization, but also that they are likely to question many of the beliefs and practices their parents had adopted. As children cannot be expelled as easily as stroppy converts, the movement could have to adapt its beliefs and practices. Furthermore, charismatic leaders die, their authority usually being replaced by a more predictable and accountable leadership. Many of the sharp boundaries that distinguished NRMs from the rest of society can become permeated by qualification and accommodation, and the movements that survive tend, though not always, to merge less noticeably into

the pluralistic smorgasbord of contemporary democracies through a process commonly referred to by sociologists as 'denominationalization.'

Reactions to NRMs

Reactions to NRMs vary across both individuals and social groups. Such reactions can range from celebratory delight, through cautious curiosity, dismissive distaste, and outright antagonism to lethal persecution. Most people have their opinions formed by reports in the mass media, which, generally speaking, tend to select the unusual, exotic, and sensational, with 'bad stories' being viewed as 'good stories.' Frequently, the media obtain their information from worried relatives, disillusioned former members, and/or the so-called anticult movement (ACM), a number of organizations devoted to exposing the perceived dangers of NRMs in an attempt to warn others and/or have the movements controlled or banned (Bromley and Hadden, 1993). Originally, many of the members of the ACM were worried relatives of converts who believed that their loved ones were in danger, but they were soon joined by others, including former members and persons such as lawyers, private detectives, politicians, mental health professionals, and counselors who had developed a specialist interest in NRMs. Anticultist activities have ranged from persons who have engaged in forcible 'deprogramming' for thousands of dollars (a practice now rarely carried out in the West, although still prevalent in Japan) to those who merely attempt to educate the general public through literature, lectures, and counseling. By 2011, the International Cultic Studies Association (originally the American Family Foundation) had become the largest and most professional such organization, but numerous other organizations have played a role in opposing NRMs around the world, examples being the Dialogue Centre in Denmark; the French Interministerial Mission for Monitoring and Combatting Cultic Deviances (MIVILUDES); the Israeli Center for Victims of Cults; the Saint Ireneus of Lyons Informational Consultative Center, affiliated to the Russian Orthodox Church; and the Chinese Association for Fighting the Evil Cults. Other 'cult-watching groups' are more scholarly in their approach, and these include CESNUR (based in Turin); the International Society for the Study of New Religions (based in Sweden); INFORM (based at the London School of Economics); and Le Center Intercantonal d'Information sur les Croyances (in Geneva), with possibly the largest collection of material related to NRMs being housed at the University of California, Santa Barbara, under the auspices of the Institute for the Study of American Religion. Peer-reviewed journals specializing in the movements include *Nova Religio*, *The International Journal for the Study of New Religion*, and *The Cultic Studies Review*.

Several government enquiries have been commissioned to look into the activities of NRMs. Russian, Israeli, French, and, to a lesser extent, Belgian reports have tended to rely either solely or predominantly on anticult resources and to recommend that the movements should be restricted, while Swedish, Dutch, and Canadian reports have paid more attention to scholarly research. Countries that require religions to register with the government in order either to gain certain privileges, or to be allowed to practice at all, usually require the religion to have a minimal number of members (Slovakia has a requirement of 20 000 members) and to have been in the country for a minimum period of time, both of which criteria tend, obviously enough, to militate against NRMs.

Throughout history there have been, and in some cases there still are, societies (such as Saudi Arabia, North Korea, and Albania under the rule of Enver Hoxha) in which if NRMs were to operate at all, they would have to do so secretly underground. Elsewhere, state reactions to NRMs can be divided roughly into two approaches. On the one hand, in countries such as France, Russia, and China, the state contends that it has to protect its citizens in advance by introducing special legislation that will prevent 'cults,' 'sects,' and/or NRMs from inflicting harm. Alternatively, societies like the United States, Canada, Britain, and Scandinavia tend toward the position that there should not be special laws related to NRMs – although if any of their members are found guilty of criminal malpractice, they are subject to the law in exactly the same way as is any other citizen.

New Urbanism

Abstract

New Urbanism is a community design movement that originated in the United States in the 1980s. It has since spread across North America and also influenced urban development and planning in other parts of the world. It promotes mixed use, mixed housing types, pedestrian-oriented streets, and high design standards. While some criticize New Urbanism for practitioners' claims that good design can build social cohesion and social capital, supporters of the movement recognize its significant contribution to designing environments intended to enhance urban quality of life.

New Urbanism is a community design movement that began with localized responses to the sprawling monotony of American development practices in the 1980s (Talen, 2005); by the turn of the millennium, New Urbanism had become extremely influential in North American planning and urban design practices and had fused with ideas related to sustainable development, smart growth, and healthy communities to dominate planning principles for urban infill and suburban green-field development (Grant, 2009). Commonly associated with principles of compact form, mixed use, mixed housing types, higher urban densities, defined center and edge, walkability, and transportation alternatives, New Urbanism has influenced policy at all levels of planning and land development, especially in fast-growing regions.

The Origins of New Urbanism

New Urbanism draws on several historical trends in community planning. Two late nineteenth century/early twentieth century movements had significant impacts on the profession of planning, and ultimately on the new design approach. With its elegant public spaces, powerful urban geometries, and classical building forms, the City Beautiful Movement, led by Daniel Burnham, contributed to rethinking civic design. It proved especially influential for American cities, stimulating grand urban center plans for cities such as Chicago; Washington, DC; and Cleveland. The Garden City Movement linked to Ebenezer Howard and Raymond Unwin inspired visions of medium-density self-contained communities blending the best of town and country: it provided the impetus for places like Letchworth Garden City in the United Kingdom; Radburn, New Jersey (USA); and Don Mills, Ontario (Canada), and became the driving concept behind suburban development for much of the twentieth century. Most important for recent design models, however, were mid-twentieth century theorists highly critical of planning and of the products of garden suburb development. In her analysis of great American cities, Jane Jacobs (1961) argued that mixed use and community diversity stimulated urban vitality while conventional planning practices and processes sucked the vibrancy from cities. Léon Krier's (1978) focus on visual coherence and historical design antecedents, and his arguments for cloning traditional urban patterns for new growth, influenced two young American architects who would play key roles in the New Urbanism movement.

In 1982, developer Robert Davis hired Andrés Duany and Elizabeth Plater-Zyberk, who had studied briefly with Krier, to prepare a plan for Seaside, a beachfront community on Florida's Gulf Coast. The design for Seaside drew on regional architectural precedents to create a compact, walkable, mixed-use community with beautiful civic spaces (Katz, 1994). The design code book for Seaside established clear standards to guide urban form to create coherence and elegance in the spaces and buildings of the community. Seaside's site plan showed historic allegiance not only to the City Beautiful designs of the late nineteenth and early twentieth centuries but also to the Beaux Arts and Baroque plans of the seventeenth and eighteenth centuries. With its photogenic pastel homes, white picket fences, and stunning civic architecture, Seaside received considerable media attention. Originally intended to be a mixed-income community with a selection of affordable housing, Seaside's success turned it into a resort destination serving the affluent.

Duany and Plater-Zyberk followed up with another award-winning community design for The Kentlands in Gaithersburg, Maryland, this time drawing on New England architectural precedents (**Figure 1**). On a large site near Washington, DC, The Kentlands featured an ambitious plan with a town center, narrow streets and service lanes, and robust mix of housing types. The project proved highly successful in the market place, although the developer's plan for the regional shopping center undermined the functioning of the main street. Housing types and styles that appeared in The Kentlands soon influenced suburban developments in many other parts of the world. By the early 1990s, neotraditional town planning was drawing considerable media and professional attention as an alternative to the stereotypical blandness and placelessness of conventional suburban form. Images of The Kentlands and Seaside provided a template for small town urbanity and set the standard for the new approach.

On the west coast of the United States, Peter Calthorpe, Douglas Kelbaugh, and their colleagues began experimenting in the 1980s with pedestrian pockets and transit-oriented development (Calthorpe, 1993; Van der Ryn and Calthorpe, 1986). These planners sought to design sustainable communities that would coordinate land use and transportation options to reduce car use and energy demand. They experimented with urban infill projects, putting new housing into inner city areas made redundant by land use change. They proposed suburban developments that could be served by public transportation

Figure 1 The Kentlands established an early benchmark for New Urbanism.

nodes. Their work gained influence among planners in large cities where deindustrialization was increasingly opening opportunities for urban redevelopment where existing transportation infrastructure could support intensification. The publication of the World Commission on the Environment and Development's (1987) report, *Our common future*, accelerated international interest in the concept of sustainable development, aimed at achieving economic development while protecting environmental quality and resources for future generations. In concert with many planners for large urban centers in Canada and Europe, the transit-oriented designers argued that resolving some of the environmental and economic problems with (sub)urban development would require increased densities and a regional planning approach: a new kind of urbanism.

In 1991, the advocates of neotraditional town planning and of transit-oriented development agreed to collaborate on what they came to call the 'New Urbanism.' They issued a joint declaration – the Ahwahnee principles – and in 1993 formed the Congress for the New Urbanism (CNU). With annual conferences and regular publications, the CNU became an important mechanism for linking and educating practitioners and spreading the messages of the movement. Developers inclined to adopt innovative community design approaches increasingly turned to New Urbanism design strategies as a way of adding cachet to their projects (Ewing, 1996). House designs emulating historic models appeared with growing frequency in new developments. Skeptical at first, professional planning organizations gradually began to develop greater interest in the planning approach.

By the late 1990s, New Urbanism principles (Table 1) were influencing community planning theory and practice in many parts of North America and Europe. New Urbanism embraced discussions about intensification (that is, increasing densities for urban efficiency and vibrancy) and compact form (that is, reducing the area for urban development), which had become central themes in discussions of sustainable development and urbanism in Europe and Canada. Although the concept of New Urbanism remained fairly closely linked to practices in the United States, similar philosophies and practices underscored movements like the urban renaissance in Britain and European urbanism (Grant, 2006).

In the late 1990s, New Urbanism found a sympathetic partner in smart growth, a movement originating among state governors in the United States who were eager to respond to rising antigrowth sentiments. Smart growth advocated many of the same planning principles as New Urbanism while suggesting that appropriate government incentives and policies could facilitate urban growth in ways that would be efficient, fiscally responsible, and attractive. New Urbanism proponents also linked with the healthy cities movement to build support for their principles. By the first decade of the twenty-first century, plans and policies for many cities reflected values and premises drawing from these interlinked discourses. New Urbanism premises had been transformed into 'good planning principles.'

Table 1 Summary of key community principles

Ahwahnee principles	*New Urbanism principles*
Complete communities	Walkability
Walking distance for mixed use	Connectivity
Transit oriented	Mixed use and diversity
Mix of housing types to accommodate diversity	Mixed housing types
Jobs for residents	Quality design
Commercial and civic center	Traditional neighborhood structure
Open space network	Increased density
Public space 24/7 use	Green transportation
Defined community edge	Sustainability
Conserve resources, conserve water, and minimize wastes	Quality of life
Design for energy efficiency	

Examples of New Urbanism communities appeared outside the United States during the 1990s. Duany and Plater-Zyberk influenced Canadian projects in Calgary (Alberta) and Markham (Ontario). McKenzie Towne in Calgary began around 1995. It was planned as a 12-phase complete town project, but after 3 phases, the developers reverted to a conventional development model. Although the project was praised for its design qualities, its location and small lot sizes in a city dominated by the oil industry proved a tough sell. Calgary planners worked assiduously to promote sustainability, transit-oriented development, and intensification, but often encountered resistance from the development industry. By the late 1990s, however, the redevelopment of a former army base in Calgary provided an opportunity to make New Urbanism work. Garrison Woods, the first phase of base conversion into urban community, proved extremely successful, selling out two years ahead of schedule. Located relatively close to the urban core, it demonstrated the viability of urban infill according to New Urbanism principles.

Begun in the mid-1990s, Cornell, in Markham, reflected the ambitions of the Ontario provincial government to stimulate urban innovation and intensification in the Toronto area. Despite financial difficulties for its developers, Cornell remained relatively true to its original New Urbanism concept through various stages of development. The Town of Markham entrenched New Urbanism principles through its municipal planning policies in the late 1990s, creating a context where no other type of development became possible. Consequently, Markham developed a reputation as a show place for New Urbanism.

Although the label of New Urbanism has been used relatively rarely outside North America, the movement clearly influenced urban developments in other parts of the world. In the early 1990s, for instance, Krier prepared the plan for Poundbury, a new community developed by the Prince of Wales on the edge of Dorchester in Dorset in the United Kingdom. Reflecting street patterns of historic British villages and an eclectic mix of architectural styles, Poundbury included provisions for 20% affordable social housing. Like an earlier generation of experimental British new towns (such as Letchworth Garden City), Poundbury attracted urban innovators and artists to its homes. To celebrate the millennium, the UK government provided funding to redevelop former industrial lands and expand some green-field sites in sustainable urban forms. Projects such as Greenwich Millennium Village in London and Upton Village in Northampton showed the potential of the urban renaissance to reshape development practices evidently influenced by New Urbanism thinking.

Advocates of New Urbanism formed organizations to promote the vision in other regions of the world: the Council for European Urbanism, the Council for Canadian Urbanism, the Australian Council for New Urbanism, etc. By the turn of the millennium, planners increasingly accepted that many of the principles associated with New Urbanism were simply good planning. Earlier ideological separations between New Urbanism, smart growth, and sustainability had largely diminished in community planning practice. Urban design and physical planning grew in importance while regulatory and zoning approaches lost currency. An upstart movement initiated by architects had helped to redefine the philosophy of the urban planning profession and the understanding of the public of how to plan and design communities.

New Urbanism Practice

New Urbanism principles have been applied to the redevelopment of brown-field (former industrial lands), gray-field (former commercial or parking lands), and green-field (former forest, farm, or scrub land) sites. In some cases, such as the early stages of McKenzie Towne in Calgary (Figure 2), the principles shaped relatively small neighborhoods of a few hundred

Figure 2 McKenzie Towne brought New England urban design to the Prairies.

homes; in some instances, such as the redevelopment of Stapleton airport in Denver, New Urbanism guided the development of large master-planned communities; in a few cases, such as the town of Markham, New Urbanism provided the framework for regulating all new development. Conventional suburban developers have often selectively adopted elements of New Urbanism design, such as traditional architectural styles, making it challenging to differentiate comprehensively planned New Urbanism communities from their imitators.

While New Urbanism played a major role in reintroducing and popularizing traditional architectural styles, its principles of mixed use, walkability, transit orientation, and high density also influenced modernist, high-rise neighborhoods. In Vancouver, the best known example of the high-rise New Urbanism model, planners and designers promoted an urban form featuring ground-oriented podium buildings with commercial uses or town houses at street level and narrow residential towers set back from the street rising high above. While it avoided traditional architectural forms, Vancouver applied policies to ensure that buildings related well to the street, included a proportion of family-oriented units, and contributed to providing 20% affordable housing. Redevelopment of extensive former industrial lands provided the city with abundant opportunities to reshape the character of urban development to promote intensification, mixed use, and design quality.

To implement New Urbanism principles, its practitioners have developed a comprehensive toolkit of strategies (Duany et al., 2010; Steuteville, 2001). New Urbanism designers use design charettes to engage community decision makers and residents in working through local issues and fashioning options for development. In the wake of the damage done by Hurricane Katrina in 2005, for instance, a group of respected practitioners led Mississippi political leaders and residents through a series of charettes to identify strategies for rebuilding communities. The concept of the transect, which differentiates urban forms, densities, and patterns according to the proximity to the center or edge of a community, has been refined to inform codes and strategies planners can use to guide development (Duany and Talen, 2002). The *SmartCode* is an open source tool reflecting New Urbanism's interest in designing form-based codes to influence the character and arrangement of urban form. While conventional land use regulation involved zoning codes that specified allowable uses and densities, form-based codes regulate buildings and spaces. As New Urbanism and smart growth have grown in influence, many local governments have begun to consider form-based codes (especially for their urban cores). In recent years, the CNU worked with the US Green Building Council to develop LEED-ND (Leadership in Energy and Environmental Design-Neighborhood Development), a rating system to evaluate new residential developments on how they address energy and environmental concerns, and with the Institute of Transportation Engineers to try to develop new guidelines for building urban streets.

Extensive application of New Urbanism principles occurred in the United States under the program Housing Opportunities for People Everywhere (HOPE) VI, initiated by the Clinton administration. HOPE intended to renew dilapidated public housing areas by rebuilding them as mixed-use and mixed-income neighborhoods. Thousands of units of public housing were demolished. Proponents of HOPE VI saw signs of social integration and economic revitalization for highly disadvantaged neighborhoods (Duany et al., 2000). Critics described gentrification, displacement, and loss of affordable housing stock for the poorest of the poor (Smith, 2002). Major initiatives to implement New Urbanism principles revealed some of the significant challenges the movement and the theory faced in achieving some of its ambitions.

Challenges and Critiques

From early in its practice, New Urbanism faced criticism that its precepts promoted environmental or architectural determinism, the idea that building form shapes behavior. Practitioners building New Urbanism projects suggested that features such as front porches on houses could generate social interactions between neighbors; corner stores or local pubs would generate a sense of community. Critics challenged the notion that architectural or civic design could achieve social objectives such as community cohesion or neighborly interaction, suggesting that human behavior reflects a wide range of social and economic factors. Theorists developing New Urbanism arguments noted that ensuring place diversity (that is, a mix of uses and housing types) might help to produce social diversity (that is, a mix of classes, household types, and ethnicities), but cautioned that design should be seen as enabling rather than generative of particular social behaviors (Talen, 2008). New Urbanism aphorisms – such as 'eyes on the street enhance security,' 'front porches promote sociability,' and 'compact form reduces vehicle travel' – have come to influence public discourse despite evidentiary challenges.

New Urbanism seeks to produce complete communities with a mix of uses, incomes, household types, and ethnicities. In the context of contemporary community design practice, such ambitions are not easy to achieve. For instance, redeveloping public housing projects to integrate other uses and market housing is described by critics as generating gentrification and displacement. Some see efforts to reurbanize the city – making city living more attractive – as forcing poorer households to the suburban fringe. New Urbanism's success in infill development and suburban new towns has not been able to deflect forces that produce social homogeneity in neighborhoods. Even in places like Markham, Ontario, or Surrey, British Columbia, where New Urbanism communities show high levels of ethnic mixing, they reveal limited socioeconomic or household type diversity (Grant and Perrott, 2009). Strategies to produce social mix do not necessarily produce positive social interactions. Planners and designers have yet to experience great success in trying to achieve social objectives through community design.

Widespread borrowing of successful architectural styles and street designs soon led to concerns about copycat communities and cookie-cutter house forms. Although some large-scale developers built comprehensive communities according to New Urbanism principles, smaller projects selectively borrowed elements of the model and generated confusion over what New Urbanism required. New England-style brownstones and turreted Victorians were duplicated in town after town, while geometric civic center street plans proliferated. Historical

features of regional architecture were sometimes adopted with poor-quality building materials and were reproduced in contexts where they were locally inappropriate. For instance, critics of Celebration, Florida – a new town built by the Disney Corporation but housing relatively few African-Americans – noted that one of its civic buildings echoed the design of the slave market in St Augustine. To try to establish a level of quality control, the CNU established registration and awards programs and worked to differentiate between projects that met the principles of the movement and those that did not. Efforts to produce and disseminate the *SmartCode* – a system to encode urban form – facilitate local development of urban design codes to replace or augment zoning regulations but may threaten to create a new level of homogeneity in urban form.

Typically accompanied by new regulatory regimes to streamline development approvals, the new methods of community design reduce NIMBYism (not-in-my-backyard syndrome) by avoiding public processes for hearing applications. New Urbanism involves community members in setting a community vision. Designers produce elegant watercolor images of promised urban landscapes to assist the decision process. Once municipal officials adopt codes and regulations, implementation falls largely to qualified experts. Instead of planning processes intended to debate the merits of individual projects – and decide whether to approve them or not – New Urbanism encourages communities to identify the desired form of development and then provides mechanisms for planners and designers to implement it without further public consultation. This reliance on the role of experts to make decisions while community residents are excluded from discussions about particular development projects has led some community engagement advocates to call New Urbanism undemocratic.

While New Urbanism gives high priority to accessibility for pedestrians – often advocating grid or modified grid street layouts to ensure connectivity of pathways – the movement has come under scrutiny over accessibility for people with impaired mobility. Because New Urbanism practitioners place homes near the street to create an urban feel for the neighborhood, they characteristically call for the main level of homes to be elevated above street level to ensure visual privacy: front doors thus require stairs but small front yards prevent construction of ramps. Efforts by advocates for persons with disabilities to ensure 'visitability' in new homes – that is, to enable persons using wheelchairs to gain access to the main floor of the house and find an accessible washroom on that level – initially met resistance from New Urbanism. Similarly, the movement weathered debates about including high-rise buildings or street patterns using one-way couplets. Although some argued that only infill development should be promoted as New Urbanism, others believed that green-field projects were essential to the market and could also be sustainable. New Urbanists have forged considerable consensus on key principles while continuing debate on aspects of implementation.

The incorporation of the terminology of smart growth, sustainability, and energy efficiency in New Urbanism masks lingering debates about development priorities and strategies. The advocates of New Urbanism believe that community design strategies have the capacity to reduce energy demand, land consumption, and automobile use. Proponents of smart growth, sustainability, and energy efficiency agree with the aims but in some cases propose alternative strategies and policies, only some of which rely on design approaches.

New Urbanism communities often feature attractive open space networks and in some cases effectively safeguard environmentally sensitive areas. At the same time, however, New Urbanism has been criticized for taking an approach to urbanism that seeks to control nature, favoring urban edges and treatments rather than naturalized waterways or parks. New Urbanism projects have been proposed or built in fragile desert and prairie landscapes. In recent years, the movement has faced challenges from Landscape Urbanism, a competing philosophy developing from landscape architecture that seeks to put landscape processes and green infrastructure into the forefront of urban development.

As a community design movement, New Urbanism competes not only with conventional development approaches but also with niche marketing approaches such as gated communities. In the later decades of the twentieth century, enclosed, limited-access enclaves became a popular development form in many countries. Gated communities promised privacy, security, and exclusivity in urban environments often perceived as dangerous, crowded, and disorderly. While New Urbanists often contrasted their own projects with gated communities, some critics noted that both movements appealed to niche markets in rapidly growing areas, produced limited social diversity, and relied on private management (often condominium corporations or homeowners' associations). Gated communities have captured a larger share of new development but as a practice gating has been much less influential on community planners and designers than has New Urbanism.

Although New Urbanism has been highly influential in shaping planning and urban design philosophies and practices in North American cities, it has faced challenges in implementation. The urban landscape reflects a built environment legacy of decades of automobile culture. Governments have proved unwilling to invest sufficient resources in transportation alternatives or in low- and moderate-cost housing to ensure mix in market projects. Successful New Urbanism communities often contribute to inflationary housing markets that exclude the mix of classes intended in the original plans. Developers may cherry-pick the elements of New Urbanism communities that they find most readily salable, thus undermining the overall quality of the product generated. Local retail uses struggle to survive in a consumer culture where big-box stores prevail. Achieving the ideal of the small and relatively self-contained urban community of the philosophy proves difficult in the context of contemporary life.

The Future of New Urbanism

New Urbanism has become thoroughly embedded in community design philosophy and practice in North America. For many influential practitioners and theorists, its premises and principles have become articles of faith, no longer subject to empirical testing or challenge. What was originally called New Urbanism now is just as likely to be labeled simply 'smart' or 'sustainable' design and planning, embedded in policies, plans, and codes in communities large and small. Although

conventional suburban forms have not disappeared, the popularization of New Urbanism increasingly influences the shape and characteristics of new developments. Just as the Garden City model contributed to spreading serpentine street networks and detached houses on large lots designed for raising children in a blend of town and country living, the New Urbanism movement helped to bring back the grid of connected streets, shape the form of streetscapes, make the town house attractive, and popularize city living. New Urbanism helped design attractive and urbane new neighborhoods and in the process contributed to the contemporary interest in moving back to the city. If the success of the Garden City model is any indication, New Urbanism is likely to experience several more decades of popularity before another community design paradigm comes along to displace it.

News Interview

Steven E Clayman, University of California, Los Angeles (UCLA), Los Angeles, CA, USA

Abstract

The news interview is a locus for direct encounters between journalists and public figures, and as such provides a window into journalistic norms, press–state relations, and other aspects of the interface between media, politics, and culture. Its history is intertwined with the coevolution of journalistic and political institutions. In its contemporary broadcast form, the study of interview questioning practices has shed light on journalistic norms regarding neutralism and adversarialism, including their boundaries of relevance, manner of implementation, and varying intensity of observance. Quantitative research indicates that adversarial questioning of US presidents is more frequent on domestic than on foreign policy matters and during downturns in the business cycle. It has also grown more frequent since the 1960s, indicating a trend toward declining deference to political authority and more adversarial relations between press and state.

The news interview is a widespread method by which journalists gather information for incorporation into scripted news stories. It is also employed as a relatively unscripted form of news in its own right, a means by which current affairs information is simultaneously generated and presented for public consumption. The latter usage is particularly important in contemporary broadcasting, as a substantial proportion of news and public affairs programming now takes the form of journalist interviewing of one or more public figures before the media audience.

In its broadcast form, the news interview has attracted scholarly attention because of its manifest significance. It is a public arena for the enactment of journalistic professionalism and the norms that bear on it. It is a forum for political communication and expressions of opinion from diverse societal interests. It both reflects and constitutes relations between journalists on the one hand, and government officials, political candidates, certified experts, and other newsworthy individuals on the other. Correspondingly, the news interview offers a fresh source of data on numerous aspects of the institutional complex of media and politics.

Defining the Broadcast News Interview

The news interview is a familiar and readily recognizable genre of broadcast programming. Its basis in comparatively spontaneous interaction distinguishes it from the fully scripted narratives and stories that have long been a staple of news. The news interview also differs from other interaction-based genres of broadcast talk (e.g., talk shows, panel discussions, etc.) by its distinctive constellation of participants, subject matter, and interactional form. In a prototypical news interview, the interviewer acts as a professional journalist rather than a partisan advocate or celebrity entertainer. Interviewees are pubic officials, experts, or others whose actions or opinions are newsworthy. The discussion normally focuses on current events, is relatively 'formal' in character, and is managed primarily through questions and answers. Prototypical examples include Meet the Press and Nightline in the USA, and Newsnight and The World at One in the UK.

Beyond this prototype are a variety of closely related but less prototypical forms, including news conferences and briefings with large numbers of journalists alternating as questioners. Somewhat farther afield are overtly partisan interviews conducted by political commentators and celebrity talk shows featuring politicians as guests. These embody the fuzzy boundaries of the news interview as a broadcast talk genre, hybrid forms combining elements of the news interview and other 'infotainment' talk show formats (Ekstrom, 2011; Hutchby, 2011).

Origins and Institutionalization

Since the news interview often involves the interface between practitioners of journalism and politics, the history of the news interview is intertwined with the coevolution of these institutions.

Although it now seems quite natural for journalists to interview elected officials and other prominent public figures, it has not always been so. In the USA, interviewing was virtually nonexistent for the first half-century of the nation's existence. Institutions of national government only gradually became publicly accessible, and even as journalists were granted access first to the House of Representatives and later the Senate, verbatim quotations were normally prohibited (Leonard, 1986). The aloofness of government officials was matched by the disinterest of most journalists. Newspapers during this period were financed by political parties and were vehicles for editorial opinion rather than reportage.

The practice of interviewing for the record can be traced to the rise of the American penny press in the 1830s, the first papers to devote themselves primarily to 'news rather than views' and to employ reporters devoted to the task of news-gathering. This new form of journalism expanded rapidly in the USA, and then more slowly in England and other European countries, in part at the prompting of American journalists in Europe. Empirical frequency should not be equated with cultural normativity; throughout the nineteenth century, interviewing was recurrently attacked as an artificial and unduly intrusive journalistic practice (Schudson, 1994).

Although these criticisms would not disappear entirely, the news interview gained greater acceptance by the early decades of the twentieth century. This development roughly coincides with the growing stature and professionalization of journalism, and the rise of 'the bully pulpit' and public relations as tools of governance (Kernell, 1997; Tulis, 1987). Accordingly, the three US presidents most responsible for institutionalizing the presidential press conference – Theodore Roosevelt, Woodrow Wilson, and Franklin Roosevelt – were each progressive reformers who used such conferences to build public support for their ambitious policies. The advent of television further increased the prominence of news interviews and press conferences, as weekly and eventually nightly news programs were devoted to journalistic questioning of public figures.

In short, what used to be regarded as extraordinary has become standard practice across the political spectrum. Just as journalists were once criticized for questioning politicians, now both officials and candidates may be subject to criticism if they fail to make themselves sufficiently accessible to journalistic questioning.

Contemporary Norms and Practices

The news interview is not merely a reflection of journalistic and political institutions; it is also a social institution in its own right. Conduct within the news interview is organized around the roles of interviewer and interviewee, and is governed by a complex matrix of social norms and conventional practices.

Participation and Turn Taking

The most fundamental and pervasive characteristic of news interview interaction is that it unfolds as a series of questions and answers between interviewers and interviewees. This is both an empirical regularity that typifies news interview talk (Heritage and Roth, 1995), and a social norm that the participants are obliged to uphold (Greatbatch, 1988). The question-framework is constitutive of the news interview as a recognizable form of interaction, distinguishing it from other varieties of broadcast talk as well as from ordinary conversation. Underlying this seemingly obvious normative framework is a less obvious substrate of practices which are necessary to produce interaction in manifest compliance with the question–answer norm (Heritage and Greatbatch, 1991). These practices include the systematic avoidance of a wide range of acknowledgment tokens and other responsive behaviors (e.g., *uh huh*, *yeah*, *okay*, *right*, *oh*, *really*) which are pervasive in ordinary conversation, but which become incongruous in a context where the parties adhere to a formal question–answer framework. Both the question–answer norm and the practices underlying it are usually taken for granted by interview participants, but they may become more conscious of the ground rules at problematic or contentious moments, when those rules may be appealed to explicitly as a means or complaint or self-defense.

News interviews are generally conducted without a co-present studio audience, and with a media audience that cannot actively participate in the encounter. The audience is nonetheless tacitly involved, both as a direct addressee during the opening and closing phases, and as a ratified 'overhearer' during the interview proper. Interviewers maintain a tacit orientation to the overhearing audience by producing explicit displays of understanding (e.g., *So you're saying thatn…*) for the audience's benefit, and by avoiding other responsive behaviors (i.e., the aforementioned receipt tokens) that would 'get between' the interviewee and the audience (Heritage, 1985).

Question Design and Journalistic Norms

In building questions, interviewers are sensitive to two further journalistic norms. On the one hand, in accordance with the ideal of objectivity, they are supposed to remain neutral. While absolute neutrality is an unattainable ideal, interviewers do strive to maintain a formally neutral or 'neutralistic' posture by restricting themselves to actions accountable as 'asking questions,' avoiding all forms of acknowledgment, and avoiding flat assertions except as prefaces to a question (Clayman, 1988) or as attributed to a third party (Clayman, 1992). Quantitative studies indicate that the overwhelming majority (>90%) of interviewer contributions in both USA (Heritage and Roth, 1995) and UK (Tolson, 2012) news interviews are neutralistically framed. At the same time, it bears emphasis that adherence to a formally neutralistic posture is no guarantee of absolute neutrality, and efforts to test for partisan bias in the distribution of questioning practices have met with some success, with bias documented in Dutch (Huls and Varwijk, 2011) but not in Swedish (Ekström et al., 2012) national contexts.

While the norm of neutralism is very broadly relevant in news interviews, it is not without limits. One boundary condition for the applicability of this norm is the domain of mainstream politics and 'legitimate issues' about which it is believed that reasonable people can disagree. Here journalists are obliged to impartially represent the divergent views of established political factions (cf Hallin, 1984). Beyond this domain, however, in areas seen as consensually admirable or deviant, journalists appear less bound by neutralism and more willing to express consensus beliefs and values via unvarnished assertions of praise or condemnation (Liebes et al., 2008). A similar orientation to societal consensus may license interviewers to correct factual errors and obviously false statements by interviewees (cf Montgomery, 2011).

A second journalistic norm bearing on question design is that of adversarialism. Consistent with the ideal of journalistic independence and the watchdog role, interviewers should not permit the public figure to transform the interview into a purely self-serving public relations event. There are various avenues by which a critical or oppositional stance can be pursued within the confines of ostensibly neutralistic 'information-seeking' questions. Questions almost always set relevant topical and action agendas, encode presuppostions, and favor particular responses; interviewers often mobilize these aspects of question design in ways that are oppositional toward the interviewee (Clayman and Heritage, 2002a). An important resource for these various forms of adversarialism is the preliminary statements that interviewers often make when leading up to a question. Such statements are justifiable as providing 'background information' necessary to render the question intelligible to the audience, but they can be deployed in ways that

allow the interviewer to maximize control over the discussion agenda, introduce substantively oppositional information, and exert pressure on recalcitrant interviewees.

The adversarialism norm has boundary conditions that are narrower than the conditions for neutralism. The norm is activated when the independent watchdog ideal becomes salient; hence, in interviews with politicians and other elite newsmakers. Political candidates receive particularly vigorous interrogative scrutiny, and campaign interviews have played an important role in recent US elections (Clayman and Romaniuk, 2011). Conversely, the norm is less relevant in interviews with nonpartisan technical experts and ordinary persons (Montgomery, 2007). Even when it is situationally relevant, adversarialism is more variably enacted than neutralism, characterizing only a minority of questions even in the contemporary era (Clayman et al., 2006). Adversarial questioning tends to be relatively muted when the topic turns to foreign affairs and national security, and when the business cycle is on the upswing (Clayman et al., 2007). And in the broader context of journalistic work practices, adversarialism is less prominent in news interviews than in subsequent story-based news coverage that interviews may receive (Eriksson and Ostman, 2013; see also Eriksson, 2011a).

Answering and Resisting

Interviewees, in responding to questions, face a different set of cross-cutting interests and pressures. Since they generally prefer to stay 'on message,' adversarial questions create an incentive for resistant or evasive responses that shift the discussion agenda in a more desirable direction. However, the normative question–answer framework obliges interviewees to answer straightforwardly, so that failure to do so can have various costs. Audience members may infer that the interviewee has some ulterior motive for avoiding the question; interviewers often counter such maneuvers with probing follow-up questions and negative sanctions (Romaniuk, 2013b; cf Eriksson, 2011b); and the acts of evasion may be singled out in subsequent news coverage (Clayman, 1990).

Accordingly, interviewees typically design their resistant responses in ways geared to minimizing these undesirable consequences (Clayman and Heritage, 2002a). They may choose to sidestep the question in an overt or explicit manner, which allows for equally explicit forms of 'damage control,' such as justificatory accounts (Ekström, 2009), and requests for permission displaying deference to the interviewer. Alternatively, when evading the question covertly, they may take steps to obscure what is transpiring by giving it the surface form of an answer. There are also techniques of resistance that can be employed by interviewees earlier, as the question is unfolding (Romaniuk, 2013a).

Question Design and Press–State Relations

How do interviewing practices, in particular those associated with vigorous and adversarial questioning, vary over time? In exploring historical trends in interviews with government officials, the study of question design becomes a window into the evolving relationship between press and state.

Adversarial questioning has risen since the 1950s in both Britain and America, although this broad trend has developed somewhat differently in these countries (Clayman and Heritage, 2002a). In Britain, a robust tradition of government regulation of broadcasting, coupled the absence of competition prior to 1958, combined to foster a highly deferential style of questioning in BBC interviews of the 1950s. When the BBC monopoly was replaced by a duopoly in 1958, the resulting competition fueled a sudden and dramatic increase in adversarial questioning. In America, where government regulation of broadcasting has been comparatively minimal and where competitive pressures have been present from the outset, adversarial questioning has grown more steadily from a higher baseline.

To track this development in the US context, Clayman and Heritage (2002b), building on previous question design research, developed a system for quantitatively assessing the level of aggressiveness in journalistic questioning. This system, as subsequently refined (Clayman et al., 2006), involves practice-based indicators for five dimensions of aggressiveness: (1) initiative, (2) directness, (3) assertiveness, (4) adversarialness, and (5) accountability.

Initial applications of this system focused on US presidential news conferences and were primarily descriptive, documenting historical trends in the aggressiveness of the White House press corps over a half-century (Clayman et al., 2006). For nine Presidents from Eisenhower through Clinton, journalists grew significantly more vigorous on all five dimensions. To some extent this transformation affected the repertoire of practices actively in use, with certain extremely deferential practices (e.g., indirect questions such as *May I ask you to talk about X*) falling out of favor, and other extremely aggressive practices (e.g., accusatory *how could you* … questions) being added to the repertoire. For the most part, however, the transformation has affected only the relative frequency of practices. Journalists have tended to exercise greater initiative via more elaborate prefaced and compound questions; the content of their questions has grown increasingly oppositional and includes greater demands for accountability; and they exert greater pressure on the president to address such content via more direct and assertive forms.

Subsequent research on the same database has been explanatory in emphasis, using multivariate analysis to identify the social conditions associated with more vigorous questioning. Significant predictors include the question content (domestic affairs questions are more aggressive than foreign affairs questions), the timing of the conference within the president's tenure in office (second terms yield more aggressive questions than first terms), and the broader economic context (questions become more aggressive when unemployment and interest rates are rising) (Clayman et al., 2007). Further, returning to the explanation of historical trends, Clayman et al. (2010) document a punctuated equilibrium pattern with the late 1960s as a turning point. Controlling for the aforementioned social conditions, questions exhibited a stable level of deference toward the president from 1953 to 1968, and then jumped abruptly to a more aggressive level from 1969 to 2000. Thus the rise of more persistent adversarialism was not a transitory response to shifting circumstances, but reflected a more fundamental and

enduring transformation of the normative tenor of president–press relations in the USA.

Whatever its causes, the growth of vigorous and adversarial questioning has transformed the broadcast news interview into a more formidable instrument of public accountability. It is now more difficult for officials and other public figures to make purely self-serving statements in an interview context. However, this revolution has stimulated a counter-revolution by public figures: increasingly sophisticated strategies of resistance and evasion, aided by a burgeoning cottage industry of media advisors and consultants (Jones, 1993). At the same time, politicians have been exploiting what is perceived as the more congenial interactive environment of 'infotainment' programs (Baum, 2005), including celebrity, comedic, and satirical talk shows (Loeb, forthcoming).

Abstract

'News' alternately refers to how news events are evaluated, reported, edited, or presented as 'news' to the audience by journalists working within an organizational context. Thus news is part of the process of telling new stories about current affairs; it is intended as an integral part of an ongoing communication to keep a given community or society informed and functioning. As a single message 'news' may be defined as something current and important to tell by widely available media which is not known in advance by an anticipated audience, and which is likely to catch the attention of a sufficient number of recipients. This definition covers both a textual 'product' and the material and economic aspects of messages as well as the technological, social, and wider cultural 'process' aspects of news stories. The news media today include newspapers, news magazines, radio, television, and Internet services. Each medium has its own form, due to some means of presentation and format which is peculiar to their dominant technology of dissemination. However, news journalism also has some common features irrespective of medium, due to similar methods and norms of retrieving information and to the forms of an effective presentation of facts.

The communication of news has been part of a storytelling tradition since time immemorial. Storytelling to a recurring public is a way of making common sense of the environment. Stories and news about people, friends, and relatives have always passed through the grapevine. Both news and rumor give nourishment for social discourse; something that can be adapted to local experiences in the company of a small group of familiar faces (*see* Rhetorical Analysis).

Definition and Background

In its modern and more formal usage 'news' refers to certain types of texts produced by the personnel, institutions, and methods of news media. The news media today include news agencies, newspapers, news magazines, radio and television, and Internet services. Each medium has its own form linked to some means of presentation, which is peculiar to their dominant technology of dissemination. However, news journalism also has some common features of content, irrespective of medium, based on similar methods of choosing stories, retrieving information, and of presenting facts effectively.

A discussion over what are the typical contents of 'news' has been a part of news sociology for as long as the subfield has existed, i.e., since the 1960s. There is not as yet any widespread agreement as to the number and kind of criteria. But researchers emphasize some qualities of news texts more often than not. News is supposed to tell something that has really happened recently, to be important for the nation or for the community, and to interest a substantial part of the audience. Thus Mitchell Stephens (1997, p. 9) defines news as 'new information about a subject of some public interest that is shared with some portion of the public.' Brian McNair (1998, p. 4) stresses that 'news claims to be (i.e., is presented to its audience as) truthful statement about, or record of, some hitherto unknown (new) feature of the actual, social world.'

Even so, journalists thrive on rumor but do not necessarily publish all that they hear. Different media may differ in what they consider a threshold for what can be made public; sometimes depending on their means of presentation, the risk of litigation, or on the ideals of journalism media adhere to. News in popular tabloids differs in many respects from news in television and in the quality press.

News as a social habit existed before the first newspaper appeared in Antwerp during a siege of the city in 1605, and even before the printed word. Tidings, rumor, and bits of information from near and far away could be learned at certain places: in the corners of a village square, in postal offices, in coffee houses and taverns, in front of churches, at the harbor, in parks etc. *Gazetta* was the name of a small Venetian coin for the price of which you could purchase a newssheet carrying commercial and other news at the Rialto Bridge in seventeenth century Venice. From the sixteenth century, and long into the nineteenth century, flysheets provided stories comparable to the sensational tabloid news of today: romantic, adventurous, and melodramatic events; supernatural phenomena; the royal court; executions, wars, and witchcraft, etc.

Regularly published newspapers, usually weeklies, were established at the beginning of the seventeenth century in England, the American colonies, Holland, Denmark, etc. They were operated by jobbing printers who also doubled as postmasters and booksellers. Since few, if any, journalists were employed, printers took their news generally from other publications, mostly from the capital, from foreign newspapers, and from letters to the editor. With regularity of publication newspapers could report continuing stories, largely as a series of minor incidents successively published. Early newspapers almost exclusively used foreign news. Censorship or the threat of censorship made local news more dangerous to publish. Over time, as censorship was eased or lifted, national news stories became a more important part of the news content (Wilke, 1987).

Periods in national media histories are sometimes linked to major changes in media technologies, in economy, and to the size of the audience, which can be compared, cross-nationally to some extent. Periodization of the developing style and

content of journalism is often linked to changes in the political system where the causal links are sometimes evident, sometimes unclear. Commonly used labels in media histories are the early elite press, the party press, the mass press, national public service versus commercial broadcasting, etc.

The development of journalism was, until the mid-nineteenth century, closely bound to the book trade, in content as well as in authors. As the press expanded in terms of the number of fully employed journalists, journalism became more distinct. Divergent and seemingly contradictory trends have been observed cross-nationally. However, a general trend seems to be toward more variety in journalistic genres and methods of expression, especially after radio and television became the fastest news media. In the USA and in many countries of Europe two basic styles of journalism has been identified since the mid-nineteenth century, one discursive and another sensational. There is simultaneously a tendency toward a 'long journalism' with a slightly 'top-down' perspective, and another toward a more grassroots-oriented 'bottom-up' populist perspective.

The first trend has produced stories set within a wider frame of time and space. In a study of worklife journalism, criminal and accident reporting in *New York Times*, the *Chicago Tribune*, and the *Oregonian* between 1894 and 1994, Barnhurst and Mutz (1997) demonstrated that reporting developed toward longer stories, wider contexts, and more analysis. The "journalists identified individuals less often by name and more often by demographic group" (Barnhurst and Mutz, 1997, p. 41). Many events nowadays do not become newsworthy unless they fit into "a longer body of interpretations and themes" (Barnhurst and Mutz, 1997, p. 41). This development has been possible by the mobilization of substantial journalistic resources, which again is dependent upon advertising revenues and upon some ownership concentration in the audience market.

The other trend – mainly for apolitical tabloids – has been toward spot news as entertainment: centered both on ordinary individuals and on celebrities set within dramatized events where persons, actions, and feelings are foregrounded. Benjamin H. Day, pioneer of the tabloid genre from the 1830s, said that "News, properly so called … must generally tell of wars and fightings, of deeds of death, and blood, of wounds and heresies, of broken heads, broken hearts, of accidents by fire or flood, a field of possessions ravaged, property purloined, wrongs inflicted, rights unavenged, reputations assailed, feelings embittered, and oppressions exercised by nations, communities, or individuals' (quoted in Huntzicker, 1999, pp. 14–15). This tabloid formula seems to have been employed in urban boulevard newspapers in all kinds of political systems except the totalitarian ones.

The News Paradigm

Social scientists often use changes in technology as an index of wider social developments. Thus, the electric telegraph – invented in 1844 – and the practice of news agencies have served a wide range of explanations of why and how journalism has changed since the mid-nineteenth century. This infrastructure is said to produce alternately: the 24-h news cycle, the 'inverted pyramid form' of presentation, and 'objectivity' in journalism. Jürgen Wilke (1984) found e.g., that between 1856 and 1906 reported events that had occurred in the past 24 h increased from 11% to 95% in the German press. The international news agencies like Reuters have been described as pioneers of neutral reporting and of the 'lead' or the inverted pyramid form (Read, 1999). Likewise, Donald Shaw (1967) explained the alleged fall of the party press in the USA in the 1880s as a result of the increasing use and dependence on wired and politically neutral news by the newspapers. Many of these explanations have been challenged recently as technological determinism, ignoring journalism as a genuinely cultural phenomenon following its own trajectory.

Richard Kaplan (1997) found, for example, that the fall of the party press in Detroit did not coincide with the increased use of wired news. Michael Schudson (1978) interpreted the rise of 'objectivity' in journalism as influenced by a philosophical pragmatism in contemporary USA at the beginning of the twentieth century and by a detached professionalism in a growing number of occupations at the time. The canon of 'objectivity' became current in the late 1920s. But even by the turn of the twentieth century establishing facts was an ideal in journalism. 'Objectivity' in addition asked for balanced facts and opinions, which required new discursive practices (*see* Journalism).

The US newspaper industry had an unprecedented growth between 1880 and 1920 with widely expanding circulation, which included new layers of society in the informed public. In combination with previous breakthroughs in paper and print technology – which made cheap copy prices possible – it transformed the press into our first mass medium. The working environment and the job definition of reporters as different from writers changed rapidly (Schudson, 1995), and the audience easily became strangers as the circulation area expanded. "Journalists were thus becoming something of a separate class, a separateness indicated by increasing numbers of articles and lectures by journalists intended to explain how the press worked" (Dicken-Garcia, 1989, p. 230).

This was also a time ripe with experiments in journalism. The various ideals, values, criteria, definitions, etc., which were eventually assimilated into the modern idea of proper news, became a way of thinking in journalism from the beginning of the twentieth century. Høyer (1995) constructs a 'news paradigm' out of five distinct elements emerging in this period: (1) the event, (2) the idea of neutral news criteria, (3) the news interview, (4) the inverted pyramid method of presentation, and (5) objectivity. This combination of journalistic methods and genres appeared gradually as separate social and cultural inventions over a period of less than 50 years. The location of most innovations was New York and London, which were also centers of applied modern newspaper technology in the latter part of the nineteenth century. The five elements can be specified as follows:

1. The event may be defined as an interaction, an accident, a meeting, a crime, etc. which ideally shall begin and end between deadlines. With regular news services and the electric telegraph the time frame of a new event became the 24-h publication cycle.
2. News criteria are the use of nonsubjective criteria for the selection of news to be published.
3. The news interview has now become the main method of collecting information. It is a peculiar kind of conversation

where the information source feels obliged to respond to inquiries, without the journalist responding psychologically since the journalsist is talking on behalf of a third – silent but more important – part: the public. This form of interview became widespread in the US press during the 1870s and 1880s and was at first met with outright disdain from the elite, since it gave newspapers more control of what should become public news (Schudson, 1994)

4. The 'inverted pyramid' is a rhetorical form. It became a standard from the 1890s. The inverted pyramid emphasizes fast and short presentation of the event, in the headlines and especially in the opening paragraph of the story, known as the 'lead.' The lead contains the major facts and actors involved. The net result of this method was stories lacking an internal chronology with implied explanations. Stories were supplied with chronologies turned downside up, and written in a dry and down-to-earth style of language, hiding the journalist as the author responsible for the story. By the flexibility of computer technology the lead technique in presentation has recently been modified. Graphics, frames for facts and summaries of previous events, etc., serve as satellites to the main story, and allow the journalist to start closer to the chronological beginning of the reported event.
5. Objectivity – or more succinctly 'balance' of information from contending sources of information – is obtained by using many different authorities as sources. The number and variety of information sources attributed is sometimes given as the operationalized definition of 'objectivity' in journalism. This form of neutrality is different from the scientific or philosophical idea of objectivity, where the quality of data is methodically evaluated and intersubjectively controlled by repetitive tests.

The 'omnibus' newspaper became the arena for these diverse innovations; it became the answer to a growing heterogeneity of newspaper readers and to their diversity of interests. Increased advertising, cheap newsprint, etc. allowed for more space for journalism and for typographical experiments. The sum of stories is implicitly supposed to tell the most important of the latest events.

There are some apparent interconnections between the diverse elements of the news paradigm. The electric telegraph, which inspired the 24-h news cycle, also gave a time frame for news stories to be fresh and new, which subdued long-winded histories with complex cause and effects linkages. The event by definition became something that happened in a very short time. The emphasis on actuality, variety, brevity, and speed easily inspires the inverted pyramid form of presentation. When facts, events, and drama are foregrounded without any explicit interpretation by the journalist, the trustworthiness of facts and opinions becomes essential. The main method of gaining authority or 'objectivity' in journalism became the news interview of expert and elite information sources.

Diachronic and International Perspectives

The technology and economics of news production soon spread to many countries, while the diffusion of 'the news paradigm' lagged behind. The marked expansion in circulation between 1880 and 1920 observed in the USA has, e.g., been documented in Denmark, Finland, and Norway (Thomsen, 1972; Tomilla 1988; Høyer, 1995). Scattered data suggest that it took several more decades before the US-inspired news paradigm became widely adapted in most European countries, except for the UK. In 1905 and 1908 major newspapers in Copenhagen and Stockholm respectively adopted 'American journalism' (Marzolf, 1982), while Jean Chalaby (1996) suggests the 1930s for France. Countries like Spain and Russia lagged even further behind for obvious reasons. The local press seems to lag behind the major cities everywhere. The historical geography of changing journalism is different from the changing media technology, even if the diffusion process has not yet been mapped out in more detail.

The most common reason given for this cultural lag between the Anglo-American world, Scandinavia, and Continental Europe is the strong tradition of a party press following a sustained period of censorship. In France and the Germanies, for example, the original ideal of a journalist was the mature gentleman of the press – the *redakteur* – commenting on the affairs of the world and interpreting trends in politics, arts and science from a given philosophical position (Esser, 1998). With regard to Central and Eastern Europe, Owen V. Johnson (1999, p. 8) points to how journalism overlapped with politics and literature from the latter half of the nineteenth century to the Soviet period. Young writers made their living as newspaper journalists until they could make their mark as writers or politicians. In contrast, the Anglo-American ideal was the outgoing aggressive news hunter unbound by political allegiances (Köcher, 1986).

These differences have been explained by the longer periods of censorship in Continental Europe, which also produced a conception of 'state-professions' as regulated by the authorities, different from the Anglo-American system. By contrast to the US journalist the German *redakteur* demonstrated independence by giving personal and informed opinions which could deviate from more officially accepted views.

Jean Chalaby (1996) focuses more on cultural factors like the sharper hierarchy of literary genres in France as compared to Britain, fostering a literary and enigmatic journalism directed toward an elite public as the interpretive community. This tradition continued for decades after censorship was abandoned (Esser, 1998; Johnson, 1999). On the other hand, the introduction of an authoritarian regime in democratic Estonia 1933–40 did not prevent the breakthrough of more modern and US-inspired journalistic methods (Harro, 2000). In Scandinavia the party press subsided gradually somewhere in the 1970s and 1980s. But even before journalistic objectivity was given priority over alternative journalistic values, other elements of the news paradigm were adopted. Nonseid and Høyer (1998) found in a content analysis of four Oslo newspapers 1908–30 only some traces of evidence for Donald Shaw's (1967) thesis that news agencies influenced journalism more generally. They studied occurrences of 'the inverted pyramid,' which became a more common story telling method during the period, both for wired and self-produced stories. But, except for the wired news, a clear majority of news throughout the period was still cast in different and older forms of story presentation. The influence of news agencies could be traced, but was weak. Alternative cultural and political factors were apparently stronger.

The former USSR had different news criteria and different concepts of autonomy in media. The media should first of all be concerned with what the public ought to know according to the communist credo. The news should depict the party line as the guideline for correct behavior. The staple news diet contained all kinds of stories about economic and social progress within socialist countries. Soviet news was not sensational and rarely reported accidents of any kind. TASS – the news bureau – provided between a third and a half of the contents of published Soviet news. In spite of this, events were not necessarily defined by the 24-h news cycle. The timing of publication was mostly bound to political routines and necessities (*see* Mass Communication: Normative Frameworks). As a reflection of this conception of what is news Halliki Harro (2000) demonstrates in a recent content analysis of Estonian newspapers 1920–99 that the 'inverted pyramid' hardly existed during the Soviet period.

These international examples demonstrate a variety that denies the simple connections between technological and cultural innovations claimed by technological determinists. Even if there may be some links between media technology and the journalism, the connection is certainly indirect and not synchronous. Media technology seems to have diffused much faster and more widely than innovations in journalism, which is 'part of, and responding to, a deeper cultural movement' (Schudson, 1991, pp. 175–189).

News in Electronic Media

Radio news started gradually in the 1920s, first by some amateur ham operators reading directly from newspapers to an unknown public. Music, and to a lesser extent lectures and humor, were the great attractions of the new medium, not news. Until the mid-1930s few journalists were assigned to radio news. Only in 1934 did news become an independent department in the British BBC (Schlesinger, 1978). Typically, at the beginning, news stories consisted of short bulletins of wired news from major news agencies.

From the outset the press tried hard to repress, and later to control, radio news. The press in Europe most often controlled the main news agencies from where broadcasting corporations got most of their news. In return for access to the wired news the press in the 1920s and early 1930s demanded that broadcasters limit transmission to one news program at around 7.00 p.m., after listeners had got their evening newspapers.

Scarcity of frequencies regulated by the state, as a common good, made public service broadcasting more vulnerable to government control compared to the press. Authorities were determined to avoid controversial topics in radio. Political parties, trade unions, and special interest organizations were thus not welcome as topics or actors in the news. This made radio news rather unrealistic and broadcasters became the voice of some unidentified official establishment.

World War II broke most of these restrictions. Backgrounds and interpretations were needed to make sense of what happened and to bolster national morale. Day-round bulletins, mixed with reportage and interviews, now became the rule. Radio reporters became identifiable persons, sometimes celebrities, as they reported directly from the war theaters. Instrumental in this process was also the taperecorder, which came into use in 1939.

Television news started out as a copy of the cinema newsreel, with presenters heard but not seen. But the audience wanted to see the faces of announcers, who eventually developed into the role of the anchorperson and moderator. The anchorperson connected the steadily differentiating parts of a televised news story: a short announcement amounting to 'headlines,' a lead-type message followed by interviews, reports from eyewitnesses or reporters on location, and expert comments back in the studio to wind up the story. A study of 17 newscasts from eight countries identified different styles of anchorpersons in Western Europe: the 'Germanic' newsreader who briefly introduces the topic and leaves the substance of information to field reporters, as contrasted to the 'Romance' moderators who provide lengthy transitions between stories and subjective comments in the style of an editorial writer (Heinderyckx, 1993).

The Internet promises a lower threshold of access to the distribution of news and views for the regular public in the industrialized world. But to be effective as a news channel it seems that the Internet so far must rely on existing networks of people with special interests. The news sites serve as points of convergence both for a like-minded public internationally and for all sorts of changing information and images within specific topic areas (*see* Information Society). Within finance and some scientific disciplines, the Internet already serves as a major publishing channel or as a marketplace for news. But for the moment it lacks the ability to reach the broader audience during a regular news cycle. For the Internet to become a general news channel, its use must expand considerably above its present level of penetration.

Neyman, Jerzy (1894–1981)

Sandy L Zabell, Northwestern University, Evanston, IL, USA

Abstract

Born in 1894, Jerzy Neyman began his career as a promising Polish statistician working in Warsaw and Crakow. After meeting Egon Pearson in the 1920s during studies abroad, Neyman began a decade-long collaboration with Pearson that led to a systematic theory of statistical tests of hypotheses. When Egon Pearson succeeded his father Karl as professor of Statistics at University College London, Neyman joined him, continuing to make fundamental contributions to the theory of statistical estimation and testing. Initially on cordial terms with R. A. Fisher, the relationship between the two deteriorated, and Neyman elected to move to the University of California, Berkeley, leading to the formation of one of the most important centers of statistics in the United States. Although Neyman continued to make important contributions to mathematical statistics after his move to the United States, his efforts largely shifted to applied statistics and departmental administration.

Neyman is best remembered today for his development of the concept of confidence interval (which supplanted Fisher's earlier fiducial formulation), and his development, largely in collaboration with Egon Pearson, of the theory of statistical hypothesis testing, involving such concepts as size and power. The mathematical clarity of his approach attracted both mathematicians and practitioners. Neyman's legendary dispute with Fisher on such matters was both long and bitter. But equally important in assessing Neyman's impact on the statistical profession was his promotion of statistics at Berkeley, helping to create one of the most important academic centers of statistical research and practice in the United States.

Life

Jerzy Neyman was born in Russia, educated in Poland, did his most important work primarily in England, and was a major figure in the development of American statistics. Although a mathematician by training and inclination, his initial work and later life were primarily devoted to applied statistics. These apparent paradoxes only become understandable in the light of Neyman's formative years.

Russia and Poland

Jerzy Splawa Neyman's early years were spent in the politically uncertain environment of the final years of the Russian Empire. He was born on 16 April 1894 to Polish parents (Czeslaw Neyman, and Kazimiera Lutoslawska) in Bendery, a city in a region of repeatedly shifting allegiances to Romania, Russia, Transnistria, and Moldova. The family was descended from Polish nobility and the 'Splawa' refers to the family coat of arms. (Neyman himself preferred not to use the prefix Splawa, and it only appears in early papers.) Neyman's grandfather Hermogenes died in connection with an uprising against the Russian authorities in 1863, and 10 of his 11 sons were exiled to Siberia. Neyman's father Czeslaw, the youngest, was spared exile, but not permitted to live in Poland. He became a lawyer and later judge in Moldova, dying when Neyman was 12 years of age. The family then moved to Kharkov, Ukraine (then part of Russia).

Initially interested in experimental physics when he entered the University of Kharkov in 1912, ineptness in the laboratory led Neyman to mathematics instead. A happy suggestion by C. K. Russyan, then giving a course of lectures at the university on the theory of functions, led Neyman to Henri Lebesgue's *Leçons sur l'intégration et la recherche des functions primitives*, and a fascination with both the Lebesgue integral and measure theory. (A long paper by Neyman on the Lebesgue integral subsequently received a gold medal of the University.) Neyman also attended lectures by the famous Russian mathematician S.N. Bernstein on probability and statistics, including its applications in agricultural experimentation. Although of little interest to Neyman at the time, this exposure to applied statistics later played a key role in Neyman's career. It was also through Bernstein that Neyman became familiar with Karl Pearson's book *The Grammar of Science*, which was influential in shaping Neyman's view of science.

Unable to serve in the military during World War I because of his poor eyesight, Neyman pursued graduate studies in mathematics in Kharkov from 1917 to 1921, interrupted briefly by an arrest in 1920 by the Russian authorities as an enemy alien. In the fall of 1920, after passing his examinations for the master's degree, Neyman became a lecturer at the University; but in 1921, fearing rearrest at the time of the Treaty of Riga between Russia and Poland, he left Kharkov and Russia for Poland and Warsaw. On 4 May 1920, he had married Olga Solodovnikova, and he brought his wife with him.

After a brief time at the National Agricultural Institute in Bydgoszcz, Poland (where his brother lived), Neyman moved to Warsaw in 1922 to work at the State Meteorological Institute. In 1923 he obtained a position at the University of Warsaw permitting him to continue his studies there, and also became a special lecturer in mathematics and statistics at the SGGW (*Szkola Glowna Gospodarstwa Wiejkiego*), Poland's Central College of Agriculture. During his time in Warsaw, Neyman came in contact with other talented Polish mathematicians of his generation, including Alfred Tarski and Antoni Zygmund. In 1924 he received his doctorate, submitting a thesis on statistical problems in agricultural experimentation; his

examiners were Wacław Sierpinski, Stefan Mazurkiewicz, and his old teacher Antoni Przeborski from Kharkov. (He was not examined in statistics, because there was no one qualified to do so, in the sense of someone knowledgeable in both research-level mathematics and applied statistical theory; Neyman was, as he later put it, 'sui generis' – a unique blend of skills in the Poland of that era.)

In 1925 Neyman obtained a postdoctoral fellowship to study under Karl Pearson at University College London, where he first met some of the leading statisticians of the day, including W.S. Gosset ('Student'), R.A. Fisher, and Egon S. Pearson (son of Karl Pearson, and an important statistician in his own right). The next year Neyman obtained a fellowship from the Rockefeller Foundation to continue his studies in Paris, where he attended mathematical lectures by Borel, Lebesgue, and Hadamard. At the same time he began a collaboration with Egon Pearson lasting more than a decade, much of it by correspondence. During the summer of 1927, Neyman returned to Poland, and resumed teaching in Warsaw and Cracow.

Neyman remained in Poland from 1928 to 1934, working in both applied and mathematical statistics. He pursued a broad range of applied statistical interests in agriculture, biology, chemistry, and socioeconomics, ultimately leading to his appointment as head of the Statistical Laboratory of the Nencki Institute of Experimental Biology. But at the same time Neyman continued to work with Egon Pearson, resulting in some of their most important papers on the theory of statistical tests.

University College London

In 1933 Karl Pearson retired as Professor of Statistics from University College. Although Fisher was Pearson's obvious choice as successor, the two had been bitter enemies for more than a decade and, in Solomonic fashion, it was decided to divide the Department into two: a Department of Genetics to be headed by Fisher (as Professor of Genetics) and a Department of Applied Statistics to be headed by Egon Pearson. Not unnaturally, Egon Pearson immediately invited his collaborator and friend Neyman to join him at University College in the new Department of Statistics, initially as a Senior Lecturer and later as Reader. Neyman accepted Pearson's offer, a decision that was to have profound consequences for his career.

Despite the tensions that immediately arose between the two Departments, Neyman initially remained on cordial terms with Fisher (as evidenced both in their personal correspondence and their 1934 exchange at a meeting of the Royal Statistical Society during the discussion of Neyman's paper on confidence intervals). But their personalities and scientific philosophies were so different that conflict between the two was inevitable. Neyman's paper (1935) on the design of experiments (which criticized some of Fisher's most important work) enraged Fisher, and the clash between the two during the discussion of Neyman's paper led to a complete and permanent severing of relations between them. (See Sabbaghi and Rubin, 2014, who note there are serious errors in Neyman's paper.) Neyman's unfortunate 1961 retrospective polemic (Neyman, 1961) provides a useful illustration of just how bitter the dispute between the two became, although it exaggerates Fisher's role prior to the 1950s: after the first several years, Fisher largely ignored Neyman in print until returning to the attack in the mid-1950s.

Berkeley

In the 1930s statisticians in the United States followed the new developments in mathematical statistics in Europe with considerable interest, founding a new journal, the *Annals of Mathematical Statistics* in 1930, and a new professional organization, the *Institute of Mathematical Statistics* (IMS) in 1935. In 1938 the *Annals* became the official publication of the IMS, and acquired a genuinely international editorial board (including Cramér, Darmois, Fisher, von Mises, and Egon Pearson). Younger U.S. statisticians visited the United Kingdom for a year or more (such as Harold Hotelling and Churchill Eisenhart), and a number of statisticians from the United Kingdom were invited to the United States to lecture.

Neyman's move to Berkeley in 1938 reflected both the climate in the United States and Neyman's personal needs. In 1937 Neyman toured the United States, lecturing both at the U.S. Department of Agriculture (at the invitation of E. Deming) and a number of major universities, resulting in the offer of a position at the University of California, Berkeley. Attracted by the opportunity to build from the ground up a statistical group, Neyman accepted the offer and permanently left London for Berkeley in 1938.

Over the next several decades Neyman used his intellectual gifts, force of personality, and international standing in the statistical community to make the University of California, Berkeley, one of the leading centers of statistical research not just in the United States, but all over the world. In 1955 the continuing expansion of Neyman's Statistical Laboratory led to the formation at Berkeley of a new and independent Department of Statistics.

Throughout his career at Berkeley, Neyman continued to vigorously promote statistics at the international level as well in the United States; particularly noteworthy in this regard were the Berkeley Symposia on Probability and Mathematical Statistics, held every 5 years from 1945 until 1970. International visitors also came to Berkeley on a regular basis, such visits often either arranged by or due to Neyman.

During his long life, Neyman received numerous honors, many of these coming after his retirement in 1961. (The retirement was in name only. In an unusual exception to Berkeley's rules regarding Emeritus status, Neyman was permitted to continue as Director of the Statistical Laboratory.) In addition to being elected a member of the National Academy of Sciences in 1964, Neyman was also elected as a foreign member of the UK Royal Society, and the Polish and Swedish Academies of Science. Other honors included medals (the U.S. Medal of Science and the Guy Medal in gold of the Royal Statistical Society), and honorary doctorates (from Berkeley, the University of Chicago, the University of Warsaw, the University of Stockholm, and the Indian Statistical Institute).

Neyman remained active to the end, running a weekly seminar at which many of his visitors and guests spoke. He died in Berkeley, California, on 5 August 1981, after a brief illness.

Scientific Contributions

Hypothesis Testing

Although Neyman wrote papers both prior to his collaboration with Egon Pearson, and many after his departure for the United States, the decade from 1928 to 1938, when he collaborated with Pearson, marked the period of his most important and lasting contributions to statistics. In order to understand their work, some background is necessary.

From a Bayesian perspective, if H_0 and H_1 are competing hypotheses, E is evidence regarding them, $P(H_0)$ and $P(H_1)$ are their probabilities prior to observing E, and $P(H_0|E)$ and $P(H_1|E)$ are their probabilities after observing E, then one form of Bayes's theorem states that

$$\frac{P(H_0|E)}{P(H_1|E)} = \frac{P(E|H_0)}{P(E|H_1)} \cdot \frac{P(H_0)}{P(H_1)}$$

that is, the posterior odds in favor of H_0 relative to H_1 are the product of the likelihood ratio of the two times their prior odds.

Historically, controversy has surrounded the use of Bayes's theorem, due to differing views regarding the nature of probability; specifically, whether it is restricted to objective frequencies or can also include subjective beliefs. If the prior odds are known (or represent given objective frequencies), then the use of Bayes's theorem is not controversial; but some statisticians reject its use if the prior probabilities represent subjective beliefs. On the other hand, in many statistical applications, the hypotheses H_0 and H_1 are statistical in nature, $P(E|H_0)$ and $P(E|H_1)$ specify objective frequencies, and the likelihood ratio of the two is not in dispute.

A classical test of significance avoids the issue of the nature and value of the initial probabilities. A null hypothesis H_0 is specified, a test statistic T is computed whose statistical distribution is specified by H_0 and which has the property that (say) larger values of T call H_0 into question. Given an observed value t of T, a p-value, $p = P(T \geq t|H_0)$, is then computed. If the value of p is small, then one is faced with a dichotomy: either an unusual event has occurred (if the null is true), or the null is false.

The odds ratio form of Bayes's theorem makes clear the limits of this approach: the level of significance only takes into account the numerator in the likelihood ratio. In particular, as Egon Pearson realized in 1926 (due to a remark by Gosset), the only justification for rejecting a hypothesis on the basis of evidence unlikely under that hypothesis is another explanation which makes the evidence more likely. Pearson then began to formulate a mathematical theory (including the distinction between simple and composite hypotheses, rejection regions, and the two types of errors); but enlisted Neyman's help, recognizing his superior mathematical abilities. This resulted in a series of five fundamental papers between 1928 and 1938 (Neyman and Pearson, 1967).

These established a rigorous mathematical framework for the modern theory of hypothesis testing. The first of these, published in 1928, introduced the concepts of two types of error (type-one and type-two error), and the likelihood ratio, using the latter to derive as special cases some of the standard tests then in use. Ironically, in light of Neyman's later violent opposition to Bayesian methods, Pearson refused to be the coauthor of a second paper, drafted by Neyman (1929), because it appealed to the use of prior probabilities. Despite this disagreement, however, their collaboration continued, and in a short period of 6 years (1933–38) they proceeded to lay the foundations of the modern theory of hypothesis testing.

Their 1933 paper, on statistical tests, formalized the process of hypothesis testing by providing a clear mathematical framework. In the case of simple hypotheses, the Neyman–Pearson lemma was stated and proved; and in the case of composite hypotheses, the concepts of similar and best critical regions were introduced. Then, in a pair of papers that appeared in 1936 they further advanced the theory by introducing the concept of unbiased critical region and illustrated the use of power curves to compare tests (Neyman and Pearson, 1936a). They then discussed the role of sufficient statistics and the novel concept of uniformly powerful tests (Neyman and Pearson, 1936b). Finally, in a last paper, in 1938 they returned to the question of the existence of unbiased critical regions.

Statistical Estimation

Traditionally, estimates such as the sample mean attach some multiple of the estimated standard error to the sample statistic as an allowance for possible sampling error. In the wake of the exact small sample theory of 'Student' (Gosset), Fisher, and others, it was realized that it was possible under certain circumstances to make assertions about such intervals independent of the unknown parameters. For example, if $X_1, \ldots, X_n$ is a sample from a normally distributed population with mean μ and variance σ^2, then Student and Fisher were able to show that if $\overline{X}$ is the sample mean and S^2 is the sample variance, then

$$T := \frac{\overline{X} - \mu}{S/\sqrt{n}} \sim t_{n-1}$$

that is, the statistic T has a distribution independent of the (in general) unknown parameters μ and σ (the 't-distribution on $n - 1$ degrees of freedom'). The importance of this is that this pivotal quantity can then be inverted to yield statements such as $(0 < \alpha < 1)$,

$$P\left(\overline{X} - c_\alpha \frac{S}{\sqrt{n}} \leq \mu \leq \overline{X} + c_\alpha \frac{S}{\sqrt{n}}\right) = 1 - \alpha,$$

where c_α is the appropriate percentile of the t-distribution. That is, the random interval $[L, R]$ (where $L = \overline{X} - c_\alpha \frac{S}{\sqrt{n}}, R = \overline{X} + c_\alpha \frac{S}{\sqrt{n}}$) has a specified coverage probability independent of the unknown parameters μ and σ^2, and therefore of any prior distribution on them.

This idea was introduced by Fisher in a paper in 1930, in which he gave a general procedure for constructing such intervals in the case of continuous distributions specified by a one-dimensional parameter. He described the probabilities generated this way as 'fiducial probabilities,' gave them the standard coverage interpretation, and noted that this could be done for every percentile θ_p, $0 < p < 1$. That is, for every p one could construct a statistic T_p such that $P(T_p > \theta_p) = p$. For any actual sample value of T_p, the function $p \to T_p$ is a distribution function in the classical sense, termed by Fisher a fiducial distribution, which he regarded as a substitute for the posterior distributions arising from the methods of inverse (i.e., Bayesian) probability. (It was this and only this point that later frequentists would reject.)

The extension of these ideas to the multiparameter case had been left open by Fisher in his 1930 paper. Neyman realized that if the essence of Fisher's method were regarded as the construction of a region which covered the unknown parameter with a specified probability, then one could easily extend the method to higher dimensions, which he proceeded to do in his 1934 Royal Statistical Society paper on sampling (Neyman, 1934), calling these 'confidence intervals' (in contrast to Fisher's terminology). At this stage, Fisher and Neyman were still on cordial terms, and the discussion after the paper was delivered was both polite and constructive, one of Fisher's main concerns being the lack of criteria for uniquely constructing such regions (which he thought of in terms of inductive inferences from data).

Originally Neyman deferred to Fisher's priority in discovering the basic underlying idea (that one could find sets having coverage probabilities independent of the parameter being estimated). But after his break with Fisher the next year, faced with both Fisher's criticism and indeed outright denial that Neyman's confidence intervals were fiducial intervals at all, Neyman proceeded on his own path, developing a complete theory of confidence intervals (Neyman, 1937). (For the evolution of Fisher's views on fiducial inference, and his dispute with Neyman, see Zabell, 1992.)

Sampling Theory

The 1934 RSS paper in which Neyman introduced the logic of confidence intervals was in fact primarily devoted to another subject, sampling theory. Even as late as the 1925 International Statistical Institute meeting in Rome, statisticians continued to debate the merits of 'purposive' versus random sampling. Neyman was a strong supporter of the use of randomization in sample selection, and his 1934 paper is commonly regarded as a turning point in the profession. Today, the best known result is his derivation of the fact that in stratified random sampling the optimal method of allocation (excluding cost) is to allocate the sample proportionately to the product of stratum size and stratum standard deviation (although the result was foreshadowed in earlier work of Chuprov). In brief, if j indexes the strata, N_j is the size of stratum j, S_j is the standard deviation of a quantity in stratum j, and n is the sample size, then one should draw.

$$n_j = n\frac{N_jS_j}{\sum_k N_kS_k}$$

elements from the jth stratum. But in fact Neyman's paper contains many other key elements of modern sampling theory, including the inclusion of cluster sampling within his framework, the importance of the sampling frame, and drawing upon whatever information is available (subjective or objective) in selecting strata, (as well as illustrating his ideas using the Galvani and Gini Italian census data).

Other Work

Neyman made many other important contributions to mathematical and applied statistics. On the mathematical side, these included his role in the Fisher–Neyman factorization criterion for suffciency, 'smooth' goodness of fit tests, best asymptotically normal estimation, and $C(\alpha)$ optimal tests of composite hypotheses; on the applied side, models for contagion, weather forecasting, and astronomy. Much of his later work was applied and done in collaboration with his long-time colleague and friend, Elizabeth Scott. He also wrote a textbook (Neyman, 1950).

Influence

It would be hard to overstate the impact that Neyman had on both the subject of modern statistics and the statistical profession. Although the English school of statistics, led by (among others) Galton, Karl Pearson, Weldon, Edgeworth, Gosset, Yule, and Fisher, both transformed the subject and vastly extended its scope, the process was undoubtedly hindered by concerns and doubts regarding both its conceptual underpinnings and rigorous mathematical structure. By advancing a purely frequentist setting for the subject, Neyman made the subject palatable to those suspicious of its Bayesian roots; and by presenting it as a natural branch of modern mathematics, using precise definitions and presenting many of its problems in purely mathematical guise, Neyman made it an attractive area of research for pure mathematicians.

This phenomenon was particularly striking in the theory of confidence intervals. Fisher's 1930 paper, 'Inverse Probability,' in which the term 'fiducial probability' first appears, had presented, in all essential respects, a general theory of confidence intervals for the one-parameter case. But as Fisher struggled to extend his approach to the multiparameter setting, many statisticians found his intuitive approach difficult to follow. Neyman, in contrast, abstracting out what he believed to be the mathematical essentials of the problem (the construction of sets that would contain a parameter with a long-term frequency independent of all unknown parameters), saw no difficulties in giving a mathematically precise extension of Fisher's approach, and did so in his 1934 paper. (It is indicative of the magnitude of the later break between the two that in his 1937 memoir on confidence intervals, Neyman not only did not cite Fisher's 1930 paper, but in a final footnote asserted that he had independently discovered the confidence interval for the t-statistic in 1930.) The conceptual and mathematical clarity of Neyman's approach eventually triumphed in statistical practice and textbook presentations (although even today the tension between the two approaches continues in the guise of the conflict between conditional and unconditional inference).

Similarly, the mathematical elegance and clarity of the Neyman–Pearson theory of tests made it the standard mode of presentation of the subject in many statistical textbooks despite Fisher's equally vehement opposition. (Fisher believed in, and indeed played a crucial role in the development of statistical tests of significance for a single null hypothesis, but thought that when more than one hypothesis was in question, parameter estimation rather than hypothesis testing was indicated.)

Closely tied to the acceptance of Neyman's approach was his impact on the statistical profession, especially in the United States. Under Neyman's leadership, the Berkeley Statistical Laboratory attracted and trained many of the leading figures in mathematical statistics in the decades immediately after the war. The Mathematical Genealogy Project lists Neyman as having 41 doctoral students and 2001 'descendants'

(students, students of students, and so on). His early students included Erich Lehmann, Joseph Hodges, and Lucien Le Cam, who themselves went on to have distinguished careers at Berkeley; their students in turn included such luminaries as Peter Bickel, Allan Birnbaum, Colin Blyth, Thomas Ferguson, Frank Hampel, and Stephen Stigler.

Literature

Many of Neyman's papers from 1923 to 1945 are conveniently collected in two volumes published in 1967 by Cambridge University and the University of California Press. Constance Reid's 1982 biography is an invaluable source of information on Neyman's life, based on extensive interviews with Neyman a few years before his death. Among the various biographical memoirs that appeared, notable are the ones by Kendall et al. (1982) for the Royal Society, and E.L. Lehmann (1994) for the U.S. National Academy of Sciences. Lehmann (2011) has also written a fair and balanced account of the contributions of both Fisher and Neyman to statistical science; see also Fienberg and Tanur (1996). For a statement of Neyman's philosophical perspective written towards the end of his life, see Neyman (1977). For his early work on agricultural experimentation and its connection with the later Rubin causal model, see Neyman (1923/1990). The history of the Department of Statistics at the University of California at Berkeley, including Neymans pivotal role, is summarized in Speed, Pitman, and Rice (2013). As they discuss, Neyman wrote a textbook (Neyman, 1950) that was used for several years there.

Abstract

This contribution is based on the assumption that there is no philosopher whose biography is as indissolubly linked with the development of his work as Nietzsche. This is why the account of the several stages of Nietzsche's life, understood as important and molding factors for his thought, will include such elements as his descent from a family of parish priests, his links with the leading personalities of his time, and both his pathogenesis and its analysis by Nietzsche himself. It is against this background that the content of his philosophical works is outlined, the more important of which will be discussed more extensively. Nietzsche's fundamental theories are outlined, as well as his philosophical ideas such as the 'superman,' 'eternal recurrence,' 'the will to power,' 're-evaluation of values,' and 'nihilism.' This contribution provides an encompassing image of Nietzsche as a philosopher, classical philologist, psychologist, and man of letters. At the same time it is focused on his importance as the philosopher of the modern age. Finally it deals with Nietzsche's effects on art, science, and especially philosophy, from his lifetime to the present.

Nietzsche was born on 10 October 1844, in Röcken near Leipzig into a family with a long tradition of pastors. A defining traumatic experience of Nietzsche's childhood was the illness and death of his father, who died in 1849 of a brain disease; Nietzsche feared suffering a similar fate his entire life. One year later the pastor's widow moved to Naumburg on the river Saale (near Leipzig) with Nietzsche and his sister Elisabeth, born in 1846. Having attended the municipal boys' school and the Gymnasium of the diocese, the 14-year-old Nietzsche was awarded a vacancy at the renowned state school Zur Pforte. Here Nietzsche received thorough instruction and showed extraordinary talent in ancient languages and German literature. He composed, wrote poems and literary treatises. The content and problems in the philosophy of the later Nietzsche were prefigured in his writings at school, which is borne out by early evidence – even earlier than the remarkable essay on *Fate and History* (1862). Texts from his tenth year of life onward inform us of Nietzsche's intellectual development, which took the form of a preoccupation with Christian religion and morality, markedly influenced by a study of Greek thought, and was pursued, for social and cultural reasons, in a highly furtive and brooding manner.

In the fall of 1864, Nietzsche began a course of study in theology and philology in Bonn; in 1865 he continued his study of philology in Leipzig and finally decided against the theological career which had been designated for him. Although an investigation concerning Diogenes Laertius submitted for a university competition was awarded a prize, Nietzsche had plans for writing a philosophical dissertation concerning Kant and even considered changing his field of study to chemistry. Neither plan came to fruition. Instead, following completion of his military service (1867–68) with the mounted canoneers in Naumburg, the 24-year-old student was unexpectedly named Professor of Classical Philology at the University of Basel in February 1869 with a recommendation from the influential teacher Friedrich Wilhelm Ritschl.

After a brief tour in the Franco–German War, broken off after some weeks due to severe illness, Nietzsche applied in January 1871 for a vacant chair of philosophy at the University of Basel, but without success. Nietzsche had close contacts to his colleague Jacob Burckhardt, whose course of lectures – later to be published under the title *Observations of World History* – he attended in the summer of 1872. He also maintained a friendship with Richard and Cosima Wagner from the very beginning of his tenure in Basel.

In *The Birth of Tragedy*, his first publication, Nietzsche interpreted Greek culture in the spirit of Schopenhauer as the result of a reconciliation between two drives which mutually cultivate and challenge one another: the Apollinian, standing for those concepts created and formed by art, and the Dionysian, being the deeper lying, formless foundation of the existence of its counterpart. Nietzsche believed that the theoretical approach to science beginning with Socrates and continuing into the present was in crass opposition to life, and hoped this approach might be overcome through Wagner's cultural-political plans. His ambition to act as a political author and educator of the German people was formative for the composition of five lectures *On the Future of Our Educational Institutions*, as well as for a series of shorter essays which were written between 1871 and 1873 and first published in the posthumous works: *Philosophy in the Tragic Age of the Greeks*, which influenced our view of pre-Socratic philosophy decisively. *On the Pathos of Truth* (1872) and *Truth and Lie in an Extra-Moral Sense* (1873) contain Nietzsche's radical critique of metaphysics and knowledge, which seeks to prove both truth and knowledge to be measures set by humans. The *Warning to all Germans* (1873) was conceived as a programmatic essay to accompany Wagner's opera festival in Bayreuth and raised the demand for a kind of *Machtpolitik* under the aegis of culture.

Between 1873 and 1876, Nietzsche published four critical essays on culture and contemporary topics, the *Untimely Meditations*: the first work contains a sharp polemic against David Friedrich Strauss, who is represented as the very model of cultural philistinism in the academic establishment of the time. Nietzsche came out against the historicism of the nineteenth century in the second work and demanded a revision of the value of history for human life, such that historical inquiry might be placed at the service of the living moment. In the

third and fourth works, Arthur Schopenhauer and Richard Wagnerare portrayed as paradigmatic examples of the unique individual with a heroic life, to which Nietzsche attached hopes for a rebirth of culture as an aesthetic unity of all life experience.

The first symptoms of physical illness had become apparent during Nietzsche's time at Pforta. Beginning in 1873, Nietzsche was plagued by ever more frequent migraine-like attacks which forced him to interrupt his teaching. In addition, Nietzsche suffered from a chronically upset stomach and severe pain in the eyes. He took a leave of absence from the university for two semesters in the fall of 1876, after various therapies and several spa-visits showed no effect on his health. The intensity and frequency of his attacks increased so dramatically that in 1879, at only 34 years of age, Nietzsche submitted a request for his dismissal from the university. He obtained a pension settlement which was unusually generous for the time, but nevertheless extremely modest. Living on his pension from the University of Basel, Nietzsche led an unstable, lonely existence in constant search of favorable climates. He spent his winters mostly on the French and Italian Rivieras (Venice, Turin, Nice), his summers in Sils-Maria in Engadin. With the exception of occasional visits to Germany, his social contact was limited almost entirely to correspondence with Lou von Salome, Paul Ree, Franz Overbeck, Carl von Gersdorff, and Heinrich Köselitz. Preoccupation with the history of his own illness was to influence Nietzsche's concepts of 'health' and 'illness' as philosophical and existential categories, and played a significant role in his diagnosis of culture.

With the publication of *Human, All-too-Human* in 1878, and following the final break with Wagner, Nietzsche completed a transition to an independent manner of thinking in the style of an exposing critique. This committed him to a new literary style – a kind of essay writing *in nuce*. In the aphoristic works *Mixed Opinions and Sayings* (1879), *The Wanderer and his Shadow* (1880) (both published in a 2nd edition as Volume 2 of *Human, All-too-Human)* and *Dawn. With Thoughts Concerning Moral Prejudices* (1881), Nietzsche achieved fundamental insights into the origin, capacity, and importance of moral acts through his genealogical and psychological method. He thus arrived at a devastating result by showing the immorality of morals. With the loss of all transcendent and historical certainties there could only be for Nietzsche an 'experimental philosophy' founded on the basis of the perspectivism of human existence, a condition of the finite worldliness of human knowledge and action. It is this 'experimental philosophy' which Nietzsche draws from physical experience in *The Gay Science* (Books 1–4, 1882).

Nietzsche created his 'ideal' of a creative combination of all human contradictions through the literary rebirth of a Persian sage in *Thus Spoke Zarathustra* (Parts 1 and 2, 1883, Part 3, 1884, Part 4 as a private publication). Here we find the conception of the *Übermensch* or superman, as well as the doctrine of the eternal return of the same. We also find a theory of the will to power as the original unity of all mental and physical strength and potential – a theory intended to lend Nietzsche's practical expectations of a revaluation of all values a metaphysical foundation.

In the years 1886 and 1887, Nietzsche began a retrospective of his previous works, some of which he edited a new, added to, and prefaced. He thereby consciously sought a connection to his previous critical and disillusioning phase, begun with the first book of aphorisms in 1878. Simultaneously, the most important critiques of morality appeared: *Beyond Good and Evil* (1886) and *On the Genealogy of Morals* (1887). In this last work Nietzsche advances the thesis that Judeo-Christian religion has not only provoked a revaluation of all values with its life-hostile morality, but that – in an erstwhile established allegiance with modern science – it threatened the future of humanity. Nietzsche saw salvation from this threat in the merciless destruction of the old values, which would thereby both overcome nihilism and make a renewed revaluation of values possible.

In 1887 came yet another serious deterioration in Nietzsche's health. He nevertheless wrote his *Hymn for Life* at the end of the year, the only musical composition he ever submitted to press, and was extraordinarily productive in the months that followed. In the spring of 1888 Nietzsche wrote *The Case of Wagner* while continuing his main work, *Will to Power*. In the course of the year 1888 he slipped into a kind of ecstatic state which was hardly burdened by sickness. This enabled him to be immensely productive. Having broken off preparations for his main work, Nietzsche concentrated with increasing haste on other projects: a summary of the main themes of the planned work, *Twilight of the Idols* (1889) and *The Antichrist* (1894), a final reckoning with Richard Wagner in *Nietzsche contra Wagner* (1894), the autobiography *Ecce Homo* (1908), and a late collection of poems, *Dionysian Dithyrambs* (1894). Signs of a growing public interest in Nietzsche's work increased, and Georg Brandes held lectures on Nietzsche in Copenhagen.

An expression of Nietzsche's emotional state in this period are effusive letters in which he predicts immanent decisions concerning his fate. He portrays himself as playing the key role in these decisions. There is evidence of a progressive loss of a realistic view of himself by the end of 1888; Nietzsche seemed to be in a delirium of exaltation. Texts and fragments from the turn of the year document a gradual crossing over into insanity. In January 1889 Nietzsche experienced a mental breakdown, and he lived thereafter in a kind of mental derangement. His physicians' diagnosis – until this day uncertain – was progressive paralysis, that is, a continual decline of the activity of the brain, presumably as the result of a latent, long-term syphilis infection.

Following Nietzsche's brief stay in the psychiatric clinic in Basel and a year-long residence at the psychiatric clinic in Jena, his mother selflessly took over his care. Nietzsche himself was in a state of progressive dementia and lost nearly all physical and mental capacities in the course of the final 10 years of his life. Nietzsche's sister took over his care at her Villa Silberblick in 1897, following the death of their mother. Nietzsche's sister's relationship to the sick man and her connection to his work were rather ambivalent, however.

At the time of his death, on 25 August 1900, in Weimar, Nietzsche had long since become a symbolic figure in European literature. Today he is, as a philosopher, the modern classic *par excellence*.

Abstract

Among well-known sociologists, Robert Nisbet was almost unique in considering himself a 'conservative.' He defined this orientation not in terms of conventional American partisan affiliation but as a sociological and anthropological perspective. Nisbet viewed human relations as requiring organic relations, which he assumed to be hierarchical and communally determined. Such relations seemed to Nisbet, natural and even beneficial; and his lifelong interest in nineteenth-century social theory and his efforts to locate organicist positions among social thinkers of the left, especially Emile Durkheim, can be attributed to an attempt to substantiate his understanding of basic human relations. Nisbet also significantly viewed contemporary America as departing rapidly and perhaps irreversibly from what he considered to be a good society. This concern pervades his studies of social theory; and it is possible to interpret his emphasis on the 'conservative' origins of sociology and his attack on leveling public administration from the 1950s onward as related reference points. Against the social disintegration and social engineering he already criticizes in his early work The Quest for Community, Nisbet poses his vision of personal authority and communal hierarchy. This vision is present in Nisbet's writings, from his early studies of French counterrevolutionary thinkers through his final assaults on America in the present age.

The author of multiple works on social theory, the history of sociology, and social commentary, Robert Alexander Nisbet might be best remembered for The Quest for Community (1953), The Sociological Tradition (1966), and The Social Bond: lntroduction to the Study of Society (1970), all books that as late as 30 years ago were being assigned as college texts. Despite his fondness for hierarchical societies, Nisbet enjoyed the respect of those who stood on the opposite side of the political divide. His literary skills and vast theoretical knowledge account for this success, as did his unmistakably utilitarian approach to social institutions.

Though Nisbet did recognize religious mystery as an integral part of its foundation, he also defended social authority from a secular perspective, that is, as necessary for civilized life and human stability. Between Prejudices: A Philosophical Dictionary (1982) and The Present Age (1988), Nisbet moved from provisional agreement with neoconservatives on policy issues back toward an older tradition of American conservatism. Throughout his career, he underlined the need for a multiplicity of local, social groups as the natural realm of human action and as a bulwark against the centralized, unitary state of the twentieth century.

After a distinguished academic career at the University of California–Riverside in his native California, Nisbet went to Columbia University as Albert Schweitzer Professor of the Humanities. Among other numerous honors, he was a recipient of the Ingersoll Prize (1985) and in 1988 the Jefferson Day lectureship of the National Endowment for the Humanities. Nisbet was also a senior fellow of the American Enterprise Institute, and with his wife Caroline, he resided in Washington where he spent his time studying in 'self-imposed isolation from political intrigue.' His best-remembered achievement may have been his works on social theory, which continue to be widely read and which document the conservative origins of nineteenth-century sociology. Sociologists, observed Nisbet, once set out to demonstrate the truth of Aristotle's axiom that man is a social being. Ironically, he wryly noted, a discipline once identified with Aristotle's view about the value of custom and inherited order has been dragged into war against social authority.

Defining Nisbet's Identity

Although some of his interpreters have assigned to Nisbet, the label 'social theorist' or historian of social ideas, that is, someone who should be remembered for having brought forth such distinguished surveys of social theory as The Sociological Tradition (1966) and The Social Philosophers (1973), Nisbet would not have settled for this designation. His work, The Social Bond (1970) is a detailed study of the sociological method of investigation; and even his widely read defense of the 'sociological tradition,' as the creation of nineteenth-century opponents of the French Revolution and the modern 'unitary state,' is intended as a vindication of Nisbet's approach to social analysis. Nisbet would not have accepted for himself the title of being a mere chronicler of ideas – as opposed to an analyst of past and present societies, who appreciated the work of the founders of his discipline.

Clearly, Nisbet did not take a statistical approach to his subject and would have shunned the comparison of sociology, which he considered at least in part an 'art form,' as opposed to a physical science or a form of applied mathematics. What characterized his field of study were a tradition of inquiry and (although he never used the term) a social epistemology. Those whom Nisbet included as social theorists viewed individuals as being shaped by their communal contexts and as acquiring identities that were derived from their group association. Because of this understanding of his discipline, Nisbet felt no compunctions about working together with Marxist Tom Bottomore in putting together a provocative anthology, A History of Sociological Analysis (1978). The two sociologists also became close friends during this period of collaboration, on the basis of what seemed to be their shared views about the social origins of human behavior and their shared dislike for the liberal-left American academy.

A Sui Generis Conservative

Significantly, even nonrightist social thinkers who were congenial to Nisbet, like Durkheim and in some respects Marx, often become through his optic identified with 'conservative insights.' The awareness of collective identities arising from communal association became for Nisbet the point of division between good and bad social theorists. And this line of division sometimes elided in his work into judgments about sound and unsound thinkers. The author who in The Social Philosophers may have been treated the most negatively is Thomas Hobbes. In the case of this seventeenth-century English philosopher, we are told that "the only units Hobbes recognized as being metaphysically real are individuals. And the only forms of social relationship he was willing to accept are those that are geometrically rigorous logic can establish as arising from the very nature of man, individual man, with his instincts and reason. That history and convention can bring into existence social relationships which deserve legitimacy by the very virtue of history and convention was a proposition utterly foreign to Hobbes's way of thinking" (1973: 137–138).

Further, Hobbes's rejection of the validity of all intermediate associations between the individual and the state is intended to glorify centralized political power. It is with deep repugnance for this project that Nisbet observes that "the state became for Hobbes a community which does not permit within itself any lesser form of community that could conceivably challenge its unity, its indivisibility, and its absolute authority" (1973: 145).

Another influential social and political theorist whom Nisbet rejected on methodological and moral grounds was Jean-Jacques Rousseau. He insists that "as many popular movements of revolt have emanated from Rousseau's revolutionary philosophy of the general will as from Marx's idea of the revolutionary proletariat a century later" (1973: 145). "Rousseau's emphasis on the community has often been interpreted in a way that is foreign to his aim" (1973: 149). In contrast to "the social community as it existed in the thought of Thomas Aquinas or, later, in the theory of Althusius," as "a community of communities an assemblage of morally integrated minor groups," Rousseau's community "is a political one, which is indistinguishable from the state and which shares all the uniformitarian qualities of the state" (1973: 149). Rousseau avails himself of the medieval organic analogy in describing his ideal government but gives it a peculiarly modern twist: "The same centralization of control which exists in the human body must dominate the structure of the community; unity is conferred by the brain, which in Rousseau's analogy represents the sovereign power. The general will is the analogue of the human mind, and as such must remain as unified and undiversified as the mind itself. The general will, as he [Rousseau] is careful to indicate, is not synonymous with the 'will of all.' It is the will of the political organism, an entity with a life of its own quite apart from that of the individual members of which it is built" (1973: 149).

Although Nisbet had less sympathetic interest in the 'individual' than the community, he tried to deal with this concept as a historical reality that must be appreciated in its own right. When he discusses the Protestant Reformation, he deplores the thoroughness with which the Reformers attacked so many of the legacies of medieval Catholicism: "To Protestants of militant determination, everything associated with Catholic medieval society—literature, art, architecture, philosophy and scholarship, as well as outright catholic theology—was suspect" (1973: 215). Yet Nisbet also exhibited great respect for the transformative religious reform that took place in sixteenth-century Europe and which began in eastern Germany and Bohemia and eventually spread by way of Switzerland into English-speaking countries. "The clear and lasting contribution of Protestantism to political, economic and social modernity: its overriding emphasis on the individual, at the expense of all external ties, bonds, symbols, and works that are the attributes of community—that is, visible community. For, as we have seen, there was a profound conviction in the minds of Luther, Calvin, and all the major Protestant reformers, that to externalize religion is to run the risk of degrading or corrupting it" (1973: 215). Nisbet also had occasional high praise for other expressions of individual consciousness, particularly, the stress on individual reliance associated with the American work ethic, and traditional liberal constitutionalism, as revealed in the work of the American framers.

It may be relevant to distinguish between Nisbet's identification as a conservative and by now inflated use of the term to refer to Republicans or self-described members of the 'conservative movement.' Nisbet never sang the glories of 'American exceptionalism' or called for the spread of the American democratic model to the rest of the globe. From The Quest for Community (1953) onward, he targeted American crusades for democracy and American popular culture. In the epilogue to The Present Age, he depicts the United States as "a giant in military resources but not in the exercise of military power and responsibility. Befuddled by belief that God intended it to be the moral teacher to the world, our giant stumbles from people to people, ever eager to demonstrate that what American touches, it makes holy" (1988: 107). America is "a giant too in domestic bureaucracy," (1988: 107) which generates an "awful total of indebtedness" (1988: 107) and growing dependence on public administration.

Although Nisbet was a true product of the New World, born and raised in Southern California, and except for wartime service in Saipan, someone who spent most of his life in Southern California and Arizona, he never praised America, the Good. He was relentlessly critical of twentieth-century American life, and although by his own admission a man of the right, he scorned a moralistic foreign policy, consumer capitalism, and managed democracy. Nisbet frequently critically comments about "progress in anarchy in modern America" (1988) and the "twilight of authority" (2000) are produced with reference to his own society, and particularly the American academy.

In the conclusion of The Quest for Community, Nisbet sums up his unseasonable thoughts about modern centralized democracy. With the modern administrative state we are dealing with a "new classification" (1970: 281). "Traditional labels—democratic, republican, capitalist, socialist, etc.—have by now become nearly as archaic as older classifications of monarchy and aristocracy" (1970: 281). What is more, "government of, by, and for the people, for all its verity as an abstract proposition, becomes nearly as irrelevant in a world

in which all despotisms rest upon foundations of mass acquiescence and where the arts of political propaganda are employed to sink the roots of government deeply in popular consciousness and participation" (1970: 281).

Going beyond the prevalent distinction between democratic and totalitarian states, Nisbet arrives at a position in Quest for Community that may be unsettling for some of his readers. He treats the difference between democratic and nondemocratic regimes as being of only secondary importance relative to other changes that were taking place: "We must conclude that all States in the future will be able to demonstrate, and will have to demonstrate attributes of socialism. But, by themselves, these will promise nothing in the way of freedom" (1970: 281). It is consolidated public administration, promoting 'equality' that Nisbet has in mind when he speaks about 'the kind of state' that is always seeking "a higher degree of centralization in the conduct of its operation, always tending toward a wider measure of politicization of social, economic, and cultural life. [The state] does not do this in the name of freedom but of freedom from want, security, and minority tyranny" (1970: 282). Nisbet's attack on the 'type of state,' in which all human and social activities, "are made aspects of the administrative structure of political government" (1970: 282) is not an allusion to a historically remote event like the Terror of the French Revolution. Nisbet has in mind an imminent threat, namely, an American government that no longer protects a "pluralism of functions and loyalties in the lives of its people" (1970: 283).

Nisbet warned against the perils of 'democratic totalitarianism' quite early in the postwar years (1970: 283). His admonitions relate to the surge of centralized power that began with the Progressive Era and which received added impetus from American participation in two World Wars and the Cold War. Significantly, these admonitions came before the vast expansion of public administration, which started in the 1960s in the United States, Western Europe, and the British Commonwealth. A development of this magnitude was only incipiently present in most Western countries until after Nisbet had become an academic celebrity. Such governmental projects as fighting discrimination and punishing hate speech were not really issues when Nisbet produced The Quest for Community. Yet, he predicted the extension of public administration into forms of thought control that were still limited to hard totalitarian states in the 1950s. The author of The Quest for Community also presciently notes that the democratic administrative state creates its own "consensus for change" (1970: 87). It achieved this goal by molding 'popular consciousness' through its command of public education. Particularly, in his recognition that the expanding modern state always claims to be representing an expansion of freedom, Nisbet was looking well beyond the post-World War II era (1970: 86).

Against Constructivism

If there is any position that suffuses Nisbet's judgments about earlier social and political theorists, it is his pervasive rejection of the notion that civil society is composed of inherently autonomous individuals. This may explain why Nisbet had such an exceedingly broad taste in social theory, ranging from Bonald, Burke, Maistre, Alexis de Tocqueville, and Georg Wilhelm Friedrich Hegel down to the French Jewish socialist Emile Durkheim. These thinkers all rejected the notion of an atomistic society and warned against a power-hungry state that does not recognize the solidarity of family and communal relations.

Unlike his other heroes, Nisbet bestowed on Durkheim an entire intellectual biography; and anyone who reads Nisbet's Sociology of Emile Durkheim (1974) will recognize the impact of this French sociologist on Nisbet's thinking. His biographical work makes generous allowances for Durkeim's decidedly leftist politics, and Nisbet expresses no negative judgment concerning Durkheim's close friendship with the Marxist socialist Jean Jaurès. Nisbet valued his subject not for his partisan political positions, but for his emphasis on organic relations. Already Durkheim's earliest major work, The Division of Labor in Society (1892) stressed the bonds uniting real people, whether through 'mechanical solidarity' in tribal societies or through a more voluntaristic 'organic solidarity' in the modern West (Nisbet, 1974: 30). The concept of individuals living apart from each other and trying to achieve autonomy outside of complex social relations seemed to Durkheim as much as Nisbet to be a pure fiction: "Durkheim rejected individualism on every possible ground. He found it insupportable as a principle of social solidarity, as an ethic or moral value, as a cornerstone of the social order, and not least as the vantage point of social analysis" (1974: 16). Nisbet infers from this attitude and Durkheim's approach to his subject evidence of his "specific criticisms of the individualistically oriented titans of his day, such as Herbert Spencer and Gabriel Tarde" (1974: 16).

We learn that in his Rules of Sociological Method (1895) and in the journal he founded in 1898 L'Année Sociologique, the distinguished Sorbonne professor raised 'structural functionalism' to the prevalent form of social research. From this vantage point, according to both Durkheim and Nisbet, the researcher can approach his area of investigation 'holistically.' Neither an unadorned 'biologism,' that is, a preoccupation with individual drives and instincts, nor an emphasis on individual action, we are warned, should guide social research. Rather the researcher should be looking at how societies function collectively.

Despite Durkheim's secularist, anticlerical politics during the French Third Republic, Nisbet points to the fact that he published a ground-breaking work on religious sociology, Elementary Forms of Religious Life (1912). His biographer lavishes praise on this study: "Of the eternality of religion resting as it does on man's differentiation of the sacred from the profane, there is not the slightest doubt in Durkheim's mind. Durkheim may well have been atheist and disbeliever. The Elementary Forms of Religious Life is nevertheless one of the most powerful statements of the functional indispensability in society ever written" (*The Sociology of Emile Durkheim* 1974: 37).

A religious skeptic, albeit formally a High Church Episcopalian, with a German Jewish grandmother, Nisbet recognized in Durkheim his oft stated appreciation of religion as a social phenomenon. He and Durkheim were both aware of the value of the 'Sacred' in man's collective existence; and in the long

section on the 'Sacred' in The Sociological Tradition, one easily detects the legacy of the author of The Elementary Forms of Religious Life. From his glowing description of this work, it is clear that Nisbet had discovered certain conceptual overlaps between his subject and himself. He accentuates Durkheim's sound views about the continuity of the Sacred, his holistic approaches to the study of social phenomena, and his understanding of organic relations as necessary for fully developed social beings. Finally, as Nisbet mentions in the closing section of the biography, he and Durkheim shared forebodings about the effects of fragmented authority, a problem that had already emerged by the second half of the nineteenth century.

There is, however, another link between the biographer and his subject. Like Durkheim, Nisbet was searching for a modern basis for community that would lead away from the dangerous collectivism depicted in Quest for Community. The prescriptions he uncovered in European counterrevolutionaries, no longer had purchase in the modern world. There was no chance of going back to a system of 'personal authority' or to status relations of the kind envisaged by Bonald or Maistre. The social bond had to be preserved or renewed in some other way, particularly in the face of expanding public administration – and given the tendency of the modern state to push certain ideas about equality into ever more extreme forms.

Nisbet did not believe that the end of the Soviet Empire and the declining appeal of Marxist–Leninism for Western intellectuals would render the egalitarian idea less compelling. Rather, he assumed the quest for equality would become even more frenetic, as the 'democratic,' planning state triumphed as a vehicle for leveling down human differences. The disintegration of an old left based on Marxism was taking place in Western countries as public administration was taking over social and economic functions once reserved to families and communities. By the time Nisbet was writing The Present Age in the late 1980s and excoriating 'the new absolutism,' he had come to believe that the accumulation of centralized political power may have become the most frightening aspect of what he referred to as 'the crisis of the present age.'

This was developing apace with what Nisbet in the same work characterized as 'the loose individual,' and in a famous, slightly sarcastic definition he lets us know: "What sociologists are prone to call social disintegration is really nothing more than the spectacle of a rising number of individuals playing fast and loose with other individuals in relationships of trust and responsibility" (1988: 87). Nisbet's tract The Degradation of the Academic Dogma (1978) may be seen as another statement of his consternation at the collapse of responsibility in a society in which communal and ancestral bonds had been frayed. The young were free to act out; professors saw themselves as political revolutionaries rather than as custodians of an inherited civilization; the only real power broker was the Hobbesian sovereign state, which increased its power with the social breakdown that was taking place all around it. Intermediate institutions were under attack.

Nisbet's preoccupation with Tocqueville's discussion of communal and familial association as the substance of American democracy in the 1830s, his focus on Durkheim's notion of mechanical solidarity, and his references to seigniorial authority among classical conservatives, were all in different ways responses to the 'crisis of the present age.' Nisbet quotes Tocqueville in The Social Philosophers in the context of a consideration of the American democracy that Tocqueville observed in his travels through the newly formed United States. Unlike centralized states in Europe, the American federal government accepted "the principle of division of authority in society" (1973: 427). This "diversification of authority" helped to keep the state from engulfing civil society (1973: 427). There was also a 'federal system of political government,' in which different branches had assigned distinctive powers at the federal level and a division of authority existed between "the national government and the government of the component states" (1973: 427). These carefully devised arrangements worked to preserve a form of democracy that was "federalist, decentralist, and pluralist" (1973: 428).

But Tocqueville, says Nisbet, also saw a 'dark side of democracy,' the propensity of democratic governments to plunge into total wars that wreck destruction on constitutional liberties and the continued possibility of divided authority (1973: 426). War, as understood by Tocqueville, who pointed here toward his interpreter, "is more likely to leave its stamp of regimentation and despotism upon societies under democracies than other types of government" (1973: 429). Although, slower to engage in wars than traditional dynastic states, democracies "are more likely, once war is under way, to extend its duration as well as its social, moral, economic, and political scope" (1973: 426). "The effect of democracy is to give a mass basis to war and to moralize it-that is, to endow it with spiritual and moral objectives that serve to hide underlying material conditions. Moreover, the centralization of government to which democracies normally tend in their process of administration is greatly enhanced by war" (1973: 426).

Structural Defects of Late Modernity

After his comments on personal authority in The Social Bond, which "strongly emphasizes the corporate solidarity of the group," Nisbet goes on to broach a gloomier topic (1970:126). He perceives "a revolution in the nature of authority" that began centuries ago and which culminated in having "personal authority superseded by territorial authority" (1970: 126). Nisbet brings this into line with another tendency that is inherent in the modern state, namely its assault on intermediate institutions as standing in the way of centralized control. The centralized state, whether or not it called itself democratic, seized on military challenges to expand its administrative reach and to manipulate isolated individuals. And as time went on, there were fewer and fewer of those safeguards that the French political theorist Bertrand de Jouvenel called 'makeweights' as a counterforce to the existing power relations.

Given this unpromising historical situation, it was natural that Nisbet looked for 'conservative' antidotes wherever they seemed usable. His analysis of Durkheim and Alexis de Tocqueville and his respectful exposition of such European conservatives as Le Comte de Bonald, Edmund Burke, and the Hegel of The Philosophy of Right all had direct bearing for him on modern American government and society. A historian of social theory, he extracted from his journeys into the past whatever concepts could be applied to understanding his own age and to addressing its problems.

This mind-set was already operative in his dissertation The Social Group and French Thought submitted at Berkeley in 1939 and dealing with the French counterrevolutionary thinkers Bonald and Maistre. Nisbet's earliest publication, which was printed in the Journal of Sociology in November 1943, together with a related treatment of the same subject in the same journal in September 1952, provides a learned discussion of social critics of the right. Nisbet became interested in these thinkers while looking for a thesis theme that he might propose to his dissertation director, the famed intellectual historian Frederick Teggart. His topic was not picked at random but reflected Nisbet's social concerns as a graduate student.

The Search to Hold Things Together

At the time he was producing The Quest for Community, Nisbet still nurtured hope that the nascent 'conservative movement,' viewed as an intellectual force, could, in the words of his friend Russell Kirk, 'redeem the times' (1988: 64). His descriptions of this hope, as stated in The Present Age, should be quoted in full because it was recalled more than 30 years later as a disastrously lost opportunity:

> A veritable renascence of conservative ideology was under way by the end of the fifties; it was sufficient to carry with it an interest in both Edmund Burke and Tocqueville greater than perhaps in any prior decade. Overwhelmingly the new conservatism—in resolute opposition to liberals above all other groups—followed Burke and Tocqueville in espousing decrease in centralization, pluralism over monism in government, the free market in basic economic production and distribution, intermediate social groups like family and local community and voluntary associations—all calculated to take some part the load of responsibility from big government—and, inevitably, substantial decrease in bureaucracy. The new conservatism also emphasized some of the traditional moral values which, it plausibly argued, had gotten battered into passivity by the forces of modernism, political modernism most of all. In a word, the *autonomy* of social order and culture was the prized objective of the new conservatism.
>
> 1988: 64

Having stated this onetime cause for optimism, Nisbet proceeded to note: "At the present time, however, militant conservatism has as little to do with its historic substance as contemporary liberalism has to do with its birthright of devotion to individual liberty. What is most likely to be labeled 'conservative' by the media—and with considerable basis in reality—in militarism on the one hand and Christian Far Right evangelicism on the other, which is far more interested today in extending the power of the state—than in a free religion in a free political society" (1988: 64). Nisbet viewed the Reagan coalition as a loose alliance of sometimes discordant ideologies, which was trying to impose a unified face on "military hawkishness, evangelicism, libertarianism, supply-siders, the power-obsessed Right" (1988: 64). He was surprised 'the Reagan coalition lasted as long as it did' and he doubted 'it will be missed' after it falls apart (1988: 64).

There is a noticeable randomness in how Nisbet goes after his targets in The Present Age. Two of his favorite targets there are the far right and the Religious Right, although we may ask whether he himself had not tried to vindicate a more rightist European conservatism than any right he attacked in his later writings. Nisbet defended counterrevolutionaries who had upheld an alliance of throne and altar. Was the modern Religious Right, which he mocked in the 1980s, more extreme in its opposition to the modern social left than were those counterrevolutionaries whose teachings Nisbet consciously drew on? One of Nisbet's favorite authors, Tocqueville, was favorably impressed on the whole by the Protestant piety and morality that he encountered during his travels in the New World.

There is a palpable looseness in how Nisbet locates his enemies, particularly in the 1980s. Was the desire for military intervention a peculiarly right-wing tendency during most of Nisbet's life? In Nisbet's youth well into his adult years, such interventionism may have been more characteristic of Democratic liberal internationalists than of right-wing Republicans, who long included in their ranks a massive isolationist wing. The neoconservatives and neoliberals of the 1980s who favored a large American military presence overseas did not come out of the far right. They saw themselves as being faithful to the liberal internationalist foreign policy of someone who may have been Nisbet's least favorite American president Woodrow Wilson. Like Wilson, later liberal internationalists were eager to 'make the world safe for democracy,' a goal that required frequent overseas intervention, although it is hard to understand why this aggressive human rights idealism should be considered typical of the far right (1988: 9).

Curiously Nisbet did not place Wilson, who was one of his arch-villains, on the right. He viewed him as first and foremost an architect of the 'new absolutism,' a topic that receives extended treatment in The Present Age: "The blunt fact is that when under Wilson America was introduced to the War State in 1917, it was also introduced to what would be later known as the total, or totalitarian, state. There is this important point to add: the acts which transformed laissez-faire, entrepreneurial America into a total state for the duration were acts of Congress, not of a revolutionary minority as in Russia and Italy" (1988: 47). In Wilson's rule Nisbet discerns the coming together of democracy and the total state. Wilson used the powers of government to push the country into a devastating European war, then regulated the economy and suppressed opposition, all in the name of fighting for democracy. Although some of his wartime measures were later suspended or rescinded, Wilson's regime from Nisbet's perspective was "a brief forerunner to the kinds of states that would be 'managerial states' in the thirties, including those known as totalitarian" (1988: 47).

This was Nisbet's conclusive judgment about a towering managerial state, with an easily scared up democratic mandate for expanding its power. This judgment may explain why Nisbet disliked the Religious Right so profoundly. It had thrown in its lot with the centralized managerial state, which it expected quite unrealistically to do its bidding. Religionists had come to worship the 'new absolutism' as much as their opponents. But no clear terminological framework was available for what Nisbet saw as the political danger of the present age. What he described lay beyond clear right–left distinctions. He was talking about a development that could be labeled in different ways, and he assigned the forces he described in The Present Age to the right or the left almost indifferently. He noted how foreign war leaders during World War I acknowledged the

thoroughness of the American effort to mobilize its population around a crusading ideology. According to Nisbet, the centralized democratic character of Wilson's regime made it easy to root out opposition, with popular approval.

He also saw a natural progression from a certain type of 'national community' to the celebration of a world government based on ideas about human rights. Both represented stages in the expansion of centralized managerial government; and in his depiction of such activist presidents as FDR, Nisbet saw the beginning of politics in a new key. FDR's 'mesmerizing idea of national community' was the attempt to enact Rousseau's vision of a sense of solidarity that could be engineered by state planners. This project, according to Nisbet, went back to the Progressive Era, and it pointed toward a planned future for humanity, which Nisbet believed he already discerned.

Given his sense of social and political desperation about lost freedoms and community, it is easy to understand Nisbet's irritation with proposed political action intended to remedy a situation he considered to have been largely created by the modern democratic state. It may also account for why he often sounded like a libertarian, particularly in his later years. This may have seemed strange for someone who had a running feud with libertarians for many decades. In the 1960s, Nisbet and Russell Kirk were singled out by the conservative libertarian Frank S. Meyer as representatives of a 'new conservatism' that exalted state power. Although it is hard to find any predilection in Nisbet for big government, it is true that he disliked libertarians as constructivists and scorners of the social bond. Some of his harshest invective was reserved for Meyer's persuasion. It is, therefore, all the more remarkable that libertarians now quote Nisbet as a critic of centralized administration and as someone who spent his life attacking the modern state. This may be because if no other reason their shared enemy.

Nomads and Nomadism in History

Abstract

Pastoral nomadism has evolved out of mixed farming. It is a form of specialization in animal production at the expense of crop growing. It may have come into being when some herds became too large for all of them to stay around a village in a radius which allowed them to come back to the village daily or in the course of a year (transhumance), and mobile camps started to move independently, comprising entire families, without fixed abodes (nomadism). Another factor which periodically has contributed to the emergence of nomadism is a decline in crop production due to climatic change. This process has occurred in history repeatedly whenever these conditions were given. Nomadism thus is not an archaic way of life but a successful adaptation to changing ecological conditions and economic opportunities.

Nomads or nomadism has often been stereotyped as violent, threatening, or primitive, and backward. On the other hand, the transition to a settled life and a sedentary economy (sedentism) was considered to be an indicator of and a prerequisite for progress and civilization. However, according to current ethnoarcheological and sociogeographical research nomadism should be considered a rather sophisticated, economically successful, and sustainable way of life practiced by inhabitants of the Old World dry belt and the reindeer nomads of the Eurasian tundra (see Khazanov and Schlee, 2012 for a comprehensive treatment of both zones; in this article the focus will be on the dry belt, the much larger zone of pastoralism and historically the much more important one because of its influence on other civilizations). In response to ecological natural and social political conditions, pastoralists have developed an optimal form of safeguarding survival by using pasture animals and adopting a mobile way of life. Given the right conditions, nomadism was able to appear or disappear again and again in different places at different times. As the article shows, this 'appearance' and 'disappearance' of the nomads runs through the entire history of the Old World dry belt, proving that nomadism is as a constitutive element of society and a resilient form of economy within the Old World dry belt. As a politicomilitary factor, as builders or destroyers of states, the influence of nomads extends far beyond the dry belt to the fertile areas all around it.

The Term 'Nomadism'

Nomadism is a specific way of life practiced in the dry belt of the Old World (**Figure 1**), a socioecological mode of culture (sozioökologische Kulturweise) (Scholz, 1995), whose internal processes, governing factors, and external appearance essentially obey the elementary 'law' of safeguarding survival. Within the Old World dry belt, nomadism was able to reappear in new and original forms, at all times and places, fundamentally separate from the evolutionary stages of sedentary life. Nomadism is oriented toward living 'in' and 'with' nature, rather than dominating and exploiting it; as such, it represents a region-specific mode of subsistence that makes optimal use of ecological possibilities and sociopolitical conditions in order to survive. Thus it is an elementary, constitutive, and independent component of the cultural and social evolution of this dryland zone.

Debatable 'Stage Theories'?

Pohlhausen (1954: pp. 153, 167) still believed that pastoral nomadism started around AD 950 and that evidence existed of its monocentrist origin. But even the extensive ethnoarcheological studies of the past decades have failed to establish when and where nomadic peoples first appeared. The emergence of nomadism – a significant event in social history – may well have been due to "the herder of the steppe and oasis farmer having broken away from his agriculturalist brother" (Wissmann, 1961: p. 28). According to Lattimore (1940) this, or a similar process, may have occurred at the Inner Asian frontier, the marginal region between settled agriculture (practiced by the Chinese) and nonsedentary livestock-keeping (practiced by the Mongols). Indeed, it could have occurred anywhere within the Old World dry belt (**Figure 1**).

Plausible concepts of the origin of nomadism have sought to convey various (three-) stage theories of cultural and economic history (Vajda, 1968). While avoiding a lengthy discussion of such explanations – which have largely outlived their relevance – mention should at least be made of Adam Smith (1723–90) and Friedrich List (1789–1846). In his comments on the evolution of 'productive forces' in agriculture, List (1961: p. 57) expressed the opinion that, in genetic terms, the nomad represents a preliminary stage before the agriculturalist. This view prevailed from the nineteenth century up to late in the twentieth century and believed to be able to locate the center of origin of nomadism in the Altai region. This theory may seem logical at first sight, but in the end it does not fit the facts and has been considered refuted since Hahn (1891: p. 487) postulated that mixed farming was the prerequisite for the origin of nomadism.

More complex theories of origin were developed by, among others, Pohlhausen (1954) or Dittmer (1965), who believed the predecessors of pastoral nomadism (Hirtennomadismus) to have been alpine mountain nomadism arising from plow

Figure 1 Nomadic livestock-keepers in the Old World dry belt (*c.*1900).

agriculture and subsequently, transhumance and cow herding (Küherwirtschaft). By contrast, Bobek (1959: p. 272) sees nomadism as a branch of clan farming (Sippenbauerntum) and relates this development 'on the one hand to the availability of extensive pasturelands that are only suitable for seasonal use and not really for permanent settlement and, on the other, to the dual economic interests of mixed farmers,' who are able 'to change their mode of subsistence relatively easily and quickly by shifting the emphasis from cultivation to animal husbandry and vice versa.' Basically similar ideas are put forward by Vajda (1968), special mention being made of the conception of a repeated alternation between nomadic and farming life as a result of natural catastrophes, armed conflicts, and economic setbacks. According to de Planhol (1975) the constant demographic surplus of the nomads substantially contributes to this situation.

These different views are plausible, but by no means imperative, in terms of time and space. The processes they describe could have happened anywhere and at any time, even long before the first written references (fourth millennium) to nomads.

Ethnoarcheological Findings

These cultural–historical views are, in the final analysis, conclusions drawn from archeological and ethnoarcheological research. Convincing work has recently been published on nomadic societies, which are generally not amenable to research methods based on permanent material evidence (Francfort, 1990). These studies have thrown light on prehistoric forms of dwellings and camps, their primary theme being the repeated alternation between sedentary agricultural and mobile livestock-keeping groups, i.e., they provide evidence of the recurring emergence of nomadic groups, of nomadism. These processes have been described for Baluchistan, for the Negev Desert, and for the Eastern Desert of Egypt. The view that the nomad did not solely evolve from the steppe farmer has been represented in various models. According to Lees and Bates (1974) the initial stage of nomadism was the transition from agriculture with animal husbandry to specialized irrigation-fed agriculture. On the one hand, this involved a population increase, specialized division of labor, and higher food requirements. On the other hand, animal husbandry was driven away from irrigable land, further and further into the steppes and mountains. Seasonal wanderings over increasing distances were the result, with nomads keeping their own separate herds. The different needs of the nomads and oasis dwellers to safeguard their existence, led to a symbiotic relationship of conflict and coexistence between the groups. The course of this relationship depended on the respective military power and was conductive to the nomads' organizational independence. With reference to Lattimore (1940), Nissen (1980: p. 287) developed a similar hypothesis regarding early

Babylonia whose history is marked by recurring invasions by 'so-called nomadic groups … in the fertile grounds.'

In fourth-millennium Sumerian texts, there are already many pointers to the repeated abandoning of agriculture in favor of mobile livestock-keeping or to the separation of livestock-keepers from agriculturalists; this process probably occurred at the start of the first millennium. Gilbert (1983) even puts forward the view that the developing urban centers the Zagros mountain region caused an increase in the demand for animal products. Simultaneously, however, more intensive agriculture was accompanied by a reduction in local animal husbandry, and niches opened up for mobile livestock-keeping and the nomadic way of life. This process is supposed to have first occurred in the seventh millennium and then again in the third and first millennia BC.

If the domestication of herd animals is accepted as the prerequisite for nomadism, then nomadism presumably did not exist in North Africa before about 5500 BC when the Sahara was a grassland niche which was increasingly occupied by pastoral people. Similarly, livestock-keeping communities would not have occurred in East Africa prior to about AD 500.

Recent archaeological evidence suggests that these dates have to be pushed back in time. While most domestic ungulates have been domesticated on the Eurasian continent and have penetrated into Africa in the care of humans, North Africa seems to have been a center of domestication of cattle of the *Bos taurus* subspecies independent of other centers of cattle domestication (The Fertile Crescent for *B. taurus* and the domestication of *Bos indicus* (the zebu) further east). Remainders of domesticated cattle in association with domesticated sorghum, other grass seeds, and pottery in the Western desert of Egypt point to cattle having been domesticated there already before 7400 BC (Wendorf and Schild, 1998). Most likely, "these cattle were first domesticated at an earlier, but unguessable, date in the Nile Valley" (Wendorf et al., 1987: p. 447). These findings push both plant domestication (agriculture) and cattle domestication back in time, without necessarily affecting their sequence. It is plausible to assume that universally, plant domestication preceded that of ungulates, as has been discussed above, in connection with the theories of different 'stages.' (For a discussion, see Schlee and Shongolo, 2012: pp. 6–10). From the time of these early agro-pastoralists onward, separations of people who specialize in livestock and become mobile may have occurred.

The transition to mobile forms of pastoralism goes along with changes in social organization. Generally, locality-based forms of organization recede and descent-based ones gain in importance. Some of the most elaborate genealogical systems (Somali and Bedouin Arabs) have been collected among pastoral nomads. Like their households, mobile pastoralists need to be able to take their group affiliations along wherever they go. A group affiliation which is primarily defined by residence in one place, however, becomes implausible when one has not been to that place for a long time.

Apart from the fact that their descent systems tend to be more elaborate, there is little commonality between pastoralists in this regard. The types of descent system they have differ widely. Patrilineal forms of descent reckoning prevail, but there are also the Tuareg where children of free-born mothers. In segmentary lineage systems, segmentation may occur whenever a man has more than one son, and smaller groups continuously become larger and genealogically deeper as new generations are added. These groups move up the scale to acquire the functions of the groups which were formerly the large ones and now have become very large and may fade away to become repositories of remote relations, while new small groups emerge at the bottom, in the growth zone, in the present where people marry and procreate. Apart from such segmentary lineage systems which are in continuous flux, there are social orders based on clans which are thought to be immutable and to have even fixed collective characters and biological peculiarities. These clans may also have higher time stability in reality, because otherwise such beliefs would have difficulties to persist.

Descent links someone to his ancestors (mostly, according to the form of descent reckoning, just one line of ancestors) and his progeny. If a descent group is narrowly defined, it severs rather than creates links to people of one's own generation. What mobile pastoralists need, however, is far reaching links to allow them to meet someone of their own (by one set of criteria or another) wherever they go. It is therefore useful to multiply the categories in which one can include someone as 'one's own.' If someone does not belong to ones patrilineal clan, he or she can belong to oneself in some other way. Links through women (affinal relations, uterine descent) are preserved by memory and appealed to when the need for that arises. Knowledge of history is also useful for pastoral strategists who seek military alliances or access to pastures in the vicinity of other groups. Descent units may have split in the past and relatives have ended up in different ethnic groups or tribes. The existence of such interethnic clan relationships may provide one with a far reaching net of relationships which one can fall back on in times of war or drought. The examples of social relations which are based on or complement and supplement shared unilineal descent could easily be multiplied.

Social institutions which systematically bridge the lines of fission between descent groups and create links between all people of one generation or similar age are the age set or generation set systems. Some of the most elaborate such systems have been recorded among pastoral groups (Boran Oromo, Maasai, and related groups). In addition to a ritual order for society which was believed to assure God's blessings like sufficient rains and protection against enemies, such systems did provide regular occasions to meet and engage in politics, and, on a smaller scale, solidarity and assistance on an individual basis, like hospitality for a traveler. Before colonial pacification it also was a means of military recruitment, and with the decline of statehood in many parts of Africa and the decentralization of violence, in many regions it has acquired that function again (Schlee, 2005).

Descent and age-grading systems, however do not appear to have satisfied the need for formalized social ties in pastoral societies. Even in setting where we find both systems, we also find a third, namely stock friendships. Giving and taking, including delayed reciprocity, are human universals. In the case of pastoral nomads, however, they are the basis of formalized institutions, namely various forms of animal loans and stock friendship. In stock friendships gifts may create obligations and loans may establish what has been called 'shared rights' in an animal. In fact, in the cases which have come to my notice, it is

not the same rights which are shared. One should rather say that different rights are held by different people in the same animal. Large stock (camels, cattle, and reindeer) may thus be the object of rather complex property regimes. The only other of objects to which similar systems of multiple rights by different sorts of holders or owners refer in preindustrial societies are land and ships. The topic 'Multiple and collective rights in animals' has been treated more fully elsewhere (Khazanov and Schlee, 2012).

It is unlikely that it will ever be known when this transition to nomadism and the forms of social organization associated with it first occurred. But what we do know is that nomadism could and did appear at different times and places, evidently unconnected with each other. It seems to have been the interplay between nature and society, together with the repeated long-term alternation of arid and less arid conditions and short dry periods since the early Holocene, that forced peoples to adopt a peripatetic way of life in order to survive. However, it is likely that social and political changes were no less important, such as the rise and fall of empires, population pressures, and famines and or tribal conflicts (Planhol, 1975). They triggered large- and small-scale migrations, caused nomadic hordes to overrun settled land, and forced settlers to move out into the steppes in times of emergency.

Historical Interpretation and Evidence

The first written reports about nomadic groups date to the fourth and third millennia. These and later scripts were almost all written by sedentary people and reflect their opinions and prejudices. Cuneiform texts, for example, always describe nomadic territory in negative terms, as the home of spirits and demons, the same word being used to denote both the desert and the underworld. In Asia the nomad is portrayed 'as a beast of hell' and 'incapable of civilized life' according to the Chinese Confucians (Khazanov, 1981: p. 142), or stereotyped as a 'barbarian,' a wolf or tiger. Little has changed since. However, now it is mainly Europeans who describe the historical role of nomads as destructive or nomadic existence as ahistorical.

The history of nomadism is voluminous, one-sided as regards its sources, doubtless complex, and difficult to unravel, and its inner contradictions have never been critically analyzed (Braudel, 1990). Its contradictory nature consists in the dichotomy between the ephemeral duration and recurrence of nomadic patterns. This will be kept in mind in the following discussion.

Historical descriptions are based on the generally accepted experience that the nomad raided settled land suddenly, like a cavalry attack, and after a while either disappeared or was assimilated. By contrast, the agriculturalist, natural conditions permitting, occupied nomadic country for permanent or at least long-term settlement and remained in logistic contact with the hinterland. Admittedly, nomads had a "considerable impact on the social and political development of many sedentary societies with more diversified economies and advanced technologies" (Khazanov, 1981: p. 142). His process gained importance as the mobility range of nomadic groups was enhanced by more powerful pack animals and the availability of lighter metal equipment. In addition, population pressure on the nomads increased, large (presumably wealthy) sedentary empires tempted nomads to trade or raid, and the scenario of conflict developed between central rule and peripheral tribes (Jettmar, 1966; Planhol, 1975). Yet these waves of nomadic raids on cultivated land are only part of the story, although sources mention them first of all. Much rarer are reports of sedentarists adopting a nomadic way of life. In this context Jettmar (1966: p. 5) even speaks of a 'victory of nomadism.' Even in Inner Asia, a region of almost classical 'antagonism' between nomads (Mongolia) and sedentarists (China), the situation is more one of overlapping and reciprocity (Lattimore, 1940: p. 328). Hence authors have spoken of an oscillation of nomadism's economic space or of a recurrent emergence of nomadism.

Indeed, empirical experience suggests that sedentism in conjunction with (oasis) agriculture offered safety and food in times of peace, but it was the mobile mode of life with herd-keeping in deserts and steppes that offered a means of survival in uncertain times. Considering the natural and socio-political settings and the short- and long-term changes occurring in the respective regions of the Old World dry belt, it may be assumed that a switch from sedentism to mobility or from agriculture to mobile livestock-keeping, and hence from agriculture to nomadism, occurred just as frequently as vice versa.

The historical view distinguishes two phases (Bobek, 1959):

1. The first phase differs only slightly from events in prehistoric times as described by archeologists. It is characterized by the keeping of small stock (sheep and goats), close links between agriculture and pastoralism, and probably also short, sometimes climate-induced switches from one to the other, leading to the recurrent separation of herders and cultivators within the same family or the same tribe. There is fairly reliable evidence of this from the Middle East. Similar events probably occurred in the Eurasian steppes although the actual 'nomadization' of the steppe agriculturalists presumably dates to the Scythian period (Iron Age, beginning around 800 BC) (Wissmann, 1961: p. 30).
2. This first phase ends during the second millennium BC. It was followed by first, domestication of the horse in the Eurasian steppes (in Turan about 2800 BC), by orienting entire peoples toward nomadism, by domestication of the camel in the Middle East (end of the second millennium), and resulting in greater mobility and the emergence of mounted warriors and hordes or 'empires' (e.g., the Cimmerians, Thracians, and Scythians, and later the Huns, Tatars, and (other) Turko-Mongolians). Second, the emergence of 'wealthy' centers of high culture, based on irrigation. They form the backdrop of the conflicts between nomadic and sedentary peoples that shape the subsequent history of this region. The clay tablets in the archives at Mari allowed scholars to infer these conflicts from the appearance of nomadic groups such as the Yaminites and Hanaeans (nineteenth century), the Sutaeans (eighteenth century), the Arameans (fourteenth century), or the Chaldeans (ninth century), in the irrigated parts of the drylands of Western Asia Mesopotamia. Lasting reminders of this are the fortified towns and villages of Iran, the famous 'walls' built as a defense against the nomadic threat in China (Great Wall, third century BC against the Huns, AD fifteenth century

against the Mongols), in phase with Turan or NE Mongolia at the mouth of the Gan, in the Middle East (Limes Syriae), North Africa (Limes Numidiae), Russia (Limes Daciae), or in central Europe (Limes Germaniae Raetiae).

In the seventeenth century BC, the Hyksos descended on Egypt, introducing the horse, and in the eleventh century the Midians overran Palestine and Canaan. Since the ninth century, the 'Arabs' (nomadizing Arab = Bedouins), mounted on camels, repeatedly entered fertile Mesopotamia and in the third century they came to Egypt. In the sixth century, the Persian Empire in the northern Middle East expanded northward (beyond the Jaxartes River) into the lands of the sedentarized steppe peoples. Like the later westward expansion of Hun rule (starting in the first century), this interrupted the sedentarization process that prevailed in the Eurasian steppes at the end of the Scythian period. Subsequently, the entire region experienced the upheavals of the migration of peoples. From then on, changes occurred more rapidly, and the nomad Bedouin continued to play a major role.

In the first two centuries AD Roman rule in the Middle East triggered a wave of nomadization; in this case the shift from a non-Bedouin to a Bedouin way of life. This process continued, as the decline of Marib Oasis (Yemen, sixth century) and the contemporaneous revival of Bedouin life show. Over the following centuries it received a new stimulus from the spread of Islam, particularly from the Islamic-Turkish nomadic armies of the Seljuqs (1048) in the mountains of Anatolia and Iran, Iranian tribes as far as Baluchistan, Sind, and Punjab, and the Beni Hilal (1051) and Beni Sulaym in North Africa. In the Khanate of the nomadic Khazars, north of the Caucasus, the sedentarization process that had begun in the eighth century was succeeded by a wave of renomadization as a result of conquests by the Pechenegs and Cumans in the eleventh and twelfth centuries. The same happened to the Polovtsy (Kipchaks) after the Mongol invasions in the thirteenth century. In the Iranian mountains, too, they triggered a real nomadization wave described as 'medieval Bedouinization' (Planhol, 1975: p. 238). The Mongol impact stretched as far as Western Asia, where for example, Baghdad was destroyed in 1258, the irrigation systems of Mesopotamia were devastated, arable land reverted to pasture, and the desert was the only safe refuge for any length of time (Wissmann, 1961: p. 47). Similar consequences followed the attacks by Timur in the fourteenth century or by the nomadic Turkmen tribes in Anatolia in the sixteenth century, where 'nomadism' disappeared in the West and began to flourish in the East (Braudel, 1990: p. 139). Until the nineteenth century Egypt experienced repeated phases of movement and settlement, and the shift between sedentarization and nomadization also continued into the nineteenth century in the Eurasian steppes, where it was quite common among the Turkmen of southern Kazakhstan for "a nomad who had lost his livestock to settle down on land, or for a rich farmer to buy a herd and to shift again to nomadism" (Khazanov, 1978: p. 121). This process has been impressively described for the Arabian Peninsula, for western Afghanistan, or for the western Sahara at the start of the twentieth century, where oasis farmers aspired to the 'higher' class of nomadic herders. With some exceptions, however, the trend since the late nineteenth century has been generally toward modern agriculture and sedentary life (Scholz, 1995).

In many instances, this trend is not caused by economic or ecological factors but by politics. Modern states, contrary to some of their medieval precursors like the empires of Chinggis Khan or Timur Leng, are not based on nomadism and do not have (former) nomads as their power elites. They are based on agriculture and on urban forms of life and share the age-old stereotypes of nomads some of which have been depicted above (see also Leder and Streck, 2005). Their main interest seems to be to control nomads, who are perceived as a security risk, and later, when the nomads no longer represent a threat, to appropriate pastoralist resources for other types of use. Also some of the historical theories described in this article affect these sedentist ideologies and policies. The conviction that nomadism represents an early development stage of humankind and stands for primitiveness and barbarism, although it has long been refuted by historians and anthropologists, lingers on in the minds of politicians and development planners. Rather than perceiving nomadism and other forms of mobile pastoralism (like long distance transhumance from a sedentary basis) as a comparatively recent development (old as they may be, they follow mixed agriculture rather than preceding it) and a sophisticated form of specialization which requires portable implements, great expertise in handling animals, flexible forms of organization (shrinking and widening forms of lineage alliance for joint defense, dispersal in times of scattered resource distribution), members of the state class tend to represent nomadism as archaic, traditionalist, unchanging, maladaptive. Anthropological studies of nomads as well as their resilience and reemergence throughout history, which has been the topic of the present article, suggest the opposite. Nomads are strategizing and opportunist users of resources in difficult environments. Recent studies (Babiker, 2013; Behnke and Kerven, 2013; Galaty, 2013) show that mobile pastoralism often compares favorably with alternative ('modern') forms of land use like irrigated agriculture, large-scale rain-fed mechanized agriculture or tourism (licensed hunting, photo-safaris) in terms of productivity per hectare, especially when one takes into account that the removal of key resources (access to riverbanks for watering, dry season pastures) often makes the use of much wider areas much less efficient or no longer feasible, so that in the interest of the overall economy pastoralist forms of production should be protected and, wherever possible, intelligently combined with other forms of land use rather than being abolished as 'archaic' or 'primitive.' Sadly, power elites often do not act in the interest of the overall economy but in their own interests and the interests of those with whom they identify with or with whom they are in alliance. This applies to the nomadic elites of Eurasian empires in antiquity and in medieval times, who were often perceived by their sedentary subjects as purely predatory, as well as to modern power elites who identify with the sedentary populations and have their own stakes in sedentary forms of economy.

Conclusions

This fragmentary outline of the 'origin' and history of nomadism may be summed up in the following four conclusions:

1. To a large extent, authors agree that stockkeeping (domestication of herd animals by farmers) forms the basis prerequisite for nomadism.
2. Historical sources 'report' in great detail, nomadic invasions of settled lands and nomadic switches to sedentism. This is probably why these events have enjoyed particular academic attention, wide and biased regard, and a historical interpretation of considerable influence on society.
3. Primarily ethnoarcheological studies have indicated that the shift from sedentary life to mobility, from agriculture to nomadism, occurred no less frequently. However, historical sources say little about such switches, and so there is some justification for assuming that insufficient importance has been attached to the historical and social relevance of these processes.
4. Nomadism is a human survival strategy in response to specific ecological and sociopolitical conditions within the Old World dry belt. As such, it represents a regionally immanent, logical 'idea' that could emerge recurrently, both locally and throughout the whole region.

The switch between sedentism and mobility, cultivator and nomad, occurred in both short- and long-term sequences, affecting both small groups and entire peoples. Its impact was local, but could also involve entire areas and regions.

In this context, it is no longer really necessary to consider Pohlhausen's (1954) hypothesis of a monocentric origin of pastoral nomadism and a multicentric origin of its various regional forms. The above archeological and historical findings, and the conclusions derived from them, suggest that it is more logical to assume that the 'idea' of a nomadic mode of culture was latent everywhere in the natural ecological and sociopolitical setting structures of the Old World dry belt. It only required a trigger, a change in prevailing conditions, for it to revive as a survival strategy or, indeed, to disappear.

Abstract

Declarative and procedural learning have been considered distinct learning systems, recruiting different brain networks. Procedural learning can be further subdivided into motor and perceptual/cognitive. A variety of tasks have been developed and used to assess specific types of procedural learning. Procedural learning involves different stages including cognitive, associative, and autonomous phases and is subject to off-line processes of consolidation. Dissociations between declarative and procedural memory deficits in patients with amnesic syndromes and neurodegenerative disorders including Parkinson's and Huntington's diseases together with evidence from brain imaging and animal studies indicated that the medial temporal lobe and basal ganglia mediate declarative and procedural learning, respectively. More recent evidence supports the notion of declarative and procedural learning as interacting rather than independent systems, depending on task demands.

Introduction

A wide spectrum of behavior is acquired through learning. The declarative memory system plays a role in the acquisition of knowledge in an intentional way including when learning facts such as the height of the Eiffel tower or a list of words. The declarative memory system is considered to operate consciously or explicitly. In contrast, the nondeclarative or procedural memory system is involved in learning motor skills such as riding a bicycle, playing tennis, or swimming, which are acquired through practice. Certain types of procedural learning are considered by some to be implicit or unconscious in nature (Butters et al., 1985; Squire, 2004). Procedural memory is the most primitive form of memory and refers to skills that are learned through acquisition of procedures, that is, associations between stimuli and responses. For example, when learning to swim, one learns the procedures, or some would say, motor programs for swimming. Once these procedures have been learned, then swimming can be performed automatically. Many of our essential motor skills in early life such as walking are acquired through procedural learning. Procedural learning is sometimes referred to as habit learning. A characteristic of procedural skill is that it can be demonstrated through action and performance, but explaining how the skill was learned is difficult, so knowledge cannot be verbally declared. For this reason, some forms of procedural learning are considered to be implicit and to occur without awareness.

As detailed below, Milner's (1962) and Corkin's (1968) seminal observations on the patient Henry Gustav Molaison, who despite dense amnesia showed intact performance on mirror tracing and pursuit manual tracking, were instrumental in fractionating the memory system. Subsequently, Cohen and Squire (1980) made a distinction between 'data-based' declarative memory and 'rule-based' procedural memory, while Graf and Schacter (1985) distinguished 'explicit' and 'implicit' memory. This led to the general view that the cortico-limbic-diencephalic structures were the substrates of declarative learning, while the striatum and its cortical projections supported procedural learning (Squire, 2004). However, in the intervening years, empirical evidence has failed to support a single procedural system and it has become clear that different types of procedural memory have distinct anatomical substrates, not solely mediated by the striatum (for review see Soliveri et al., 1992; Squire, 1987). Furthermore, recent evidence (e.g., Poldrack et al., 2001; Schendan et al., 2003) suggests that the declarative and procedural systems play an interactive rather than independent role in learning and development of skill.

Types of Procedural Memory and Tasks Used for Assessment

Studying lists of words followed by immediate or delayed word recall is the most common method for assessing short- and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51052-6

long-term declarative memory in the laboratory. Skill learning is a relatively less intuitive phenomenon to measure. Nevertheless, over the years, numerous tasks have been developed to specifically assess procedural learning. Some of these procedural learning paradigms involve tasks that recruit the motor system directly, while others involve nonmotor tasks that have no direct motor component per se, but recruit the procedural system due to the nature of the complex information being learned during task performance and the fact that the knowledge becomes automatized and habitual.

Motor Procedural Skill Learning Tasks

1. *Mirror tracing*: This visual-motor task involves learning the new motor skill of drawing a figure (e.g., a star shape) by looking at its reflection in the mirror (Milner, 1962). The presentation of familiar but distorted visual information, which must be 'translated' before an accurate response can be made is the reason why this task is considered to involve procedural learning; once a participant has figured out how to draw the image in the mirror the first time, i.e., acquired the appropriate procedures, they will have little difficulty the second time they complete the task.
2. *Pursuit rotor*: The participants are instructed to keep a metal stylus in contact with a rotating disc. The amount of time on target typically increases with practice, and the acquired skill transfers to subsequent test occasions (Corkin, 1968).
3. *Tracking tasks*: The participants' task is to track the movements of a target (e.g., small rectangle) presented on a screen by moving the position of a pointer also presented on the screen. The difficulty of tracking can be manipulated by presenting various types of target. The percent time on target is measured which improves with practice.
4. *Serial reaction time task* (SRT task): This is a paradigm that has been employed extensively to study procedural/implicit motor sequence learning. The SRT task was developed by Nissen and Bullemer (1987). The SRT task involves presentation of stimuli in one of several target locations (e.g., in four horizontally presented boxes), to which participants respond as quickly as possible by pressing corresponding response buttons. Typically, participants perform several hundred trials of what is essentially a choice reaction time (RT) task; although unbeknownst to them, the targets actually appear in a predetermined, repeating sequence of locations (e.g., 3-4-2-3-1-2-1-4-3-2-4-1), the presentation of which is interspersed with random or pseudo-random trials. Following SRT training blocks, sequence learning is demonstrated by faster reaction times (RTs) to sequence compared to random blocks of trials. Learning on the SRT task is considered by some to be implicit and operating outside of awareness because it occurs incidentally and participants perform poorly on subsequent tests of awareness such as verbal report of their acquired sequence knowledge.

Perceptual or Cognitive Procedural Skill Learning Tasks

1. *Mirror reading*: This task assesses the ability to learn to read mirror-reversed material. Without the participants' knowledge, some of the stimuli are repeated. The rate of learning can therefore be assessed for both new material and repeated stimuli. As with mirror tracing, the task involves acquiring the procedures for translating familiar but distorted visual information before an accurate response can be made.
2. *Prism adaptation*: In this task, the participant wears prisms that produce a consistent, usually lateral, distortion of visual input. Initially, visually guided motor behavior is disturbed as the movement is based on the distorted visual information. With experience, the motor response adapts. That true perceptuo-motor adaptation has occurred (and not merely development of a conscious strategic change), becomes evident when the prisms are removed. When the prisms are removed, normal participants misreach in the opposite direction for a few trials before the visuo-motor system is 'retuned.' This 'negative after-effect' is the main criterion for determining that adaptation had taken place.
3. *Priming*: Priming refers to the facilitative effect of a pre-exposure to an item on subsequent processing of the same item (Schacter and Graf, 1986). Various tasks have been used to assess diverse types of priming, including perceptual priming, word stem completion, and semantic priming. In a typical perceptual priming task, for example, the stimuli employed are incomplete pictures (Gollin figures) or fragmented words. The participants try to identify the stimulus, starting with the most incomplete word/figure. If they fail, a more complete stimulus is presented. This process continues until identification occurs. Repeated testing on the same material in healthy participants leads to rapid learning, with participants being able to identify even the most degraded stimuli.
4. *Weather prediction task*: The weather prediction task (WPT) is a nonmotor probabilistic classification task involving incremental learning of a complex probabilistic rule (Knowlton et al., 1994). On each trial, participants are presented with a particular arrangement of one, two, or three of four possible tarot cards, each of which have different patterns on them (e.g., squares, diamonds, circles, or triangles). Participants are required to use the cards presented on each trial to predict a binary outcome; whether the weather will be rainy or fine. Each of the four cards is independently associated with the two possible outcomes with a fixed probability and overall, each outcome occurs equally often. For example, the squares, diamonds, circles, and triangles respectively predict the outcome 'fine' with a fixed probability of 0.2, 0.4, 0.6, and 0.8. Typically, participants perform around 200 trials of the WPT with corrective feedback on each trial. By learning the independent cue–outcome associations across trials, participants can improve their predictive accuracy on the WPT across training trials. Learning on the WPT task is considered by some to be implicit operating outside of awareness because participants perform poorly on subsequent tests of awareness.
5. *Classical conditioning*: Eyeblink conditioning is a form of classical conditioning that has been employed to study unconscious learning. This consists of pairing an auditory or visual stimulus (the conditioned stimulus – CS) with an

eyeblink-eliciting unconditioned stimulus (US) (e.g., a mild puff of air to the cornea). Participants initially produce a reflexive, unconditioned response (eyeblink) that follows US onset. After many CS–US pairings, an association is formed such that an eyeblink, or conditioned response, occurs and precedes US onset. The magnitude of learning is generally gauged by the percentage of all paired CS–US trials that result in a conditioned response.

Processes and Mechanisms of Procedural Learning

Stages of Learning

Most cognitive models of skill acquisition distinguish different phases of learning, involving distinct processes and modes of representation. Although the details differ, most of these models distinguish an initial phase requiring attention, conscious processing, working memory, and hypothesis testing with a later less demanding automatic phase. For example, Adams (1971) distinguished 'verbal-motor' and 'motor' stages, while Logan (1988) described 'algorithm-based' and 'memory-based' performance. Fitts (1954) hypothesized three main stages of skill learning. In the first 'cognitive phase' that requires attention, an individual develops an understanding of the demands of the task at hand, by breaking down the skill to be learned into its component parts and learning the basic procedures to be followed. The second 'associative phase' involves repeated practice of the task until successful patterns of responding emerge. Through reliance on feedback, in this associative phase, task components that lead to success are retained whereas components that are ineffective are dropped. The final 'autonomous phase' involves perfecting the acquired skill so that it can be performed quickly and automatically, without conscious attention.

Evidence from a study involving single-cell recordings from neurons in the striatum and motor cortex during motor skill learning in mice indicates there are different firing patterns in the motor system depending on whether skill learning is fast (learning that occurred during the first training session) relative to slow (learning that occurred across sessions). For example, during the first fast learning session, there was parallel activation of neurons in the striatum and motor cortex, whereas when the learning was slow the neuronal firing was differential in these structures rather than comparable (Costa et al., 2004). These findings could be considered as direct evidence for different neural signatures for the associative (fast) and associative/autonomous (slow) phases in Fitts' model.

Importance of Practice for the Development of Skill

A feature of procedural learning is that repetition and practice are important for the acquisition of skill, which is most evident in the case of motor skills. The importance of practice is reflected in Schmidt's (1982) definition of motor learning as "a set of processes associated with practice or experience leading to relatively permanent changes in the capability for responding." In this definition, "the permanent changes in the capability for responding" as indicative of learning distinguishes this from 'performance' reflected in transient changes in behavior. A recent primate study (Picard et al., 2013) examined changes in metabolic and single-neuronal activity in the motor cortex, with long-term training over 1–6 years of internally generated and visually guided sequences of reaching movements. A significant reduction of metabolic activity in the motor cortex was observed for the performance of internally generated compared to visually guided task, suggesting that extended practice results in reduction in the synaptic activity required to produce internally generated sequences of movement. It was concluded that practice leading to skilled performance is associated with more efficient generation of neuronal activity in the motor cortex.

Equally important for learning to occur are feedback and knowledge of results. Feedback can be intrinsic (produced by the response and could be visual, auditory, or proprioceptive) or external (provision of augmented information about performance by an external source) with the latter often referred to as knowledge of results. Less well known is the benefit that randomized (high contextual interference) versus grouped/constant (low contextual interference) training schedules can have on long-term skill acquired through practice. Termed the 'contextual interference effect,' this somewhat counter-intuitive benefit refers to the observation that higher levels of contextual interference, for example, when several tasks are being learned and practiced at the same time, result in poorer practice performance, but are associated with superior learning, retention, and transfer. This benefit has been demonstrated for a range of tasks, motor skills acquired explicitly and implicitly, and across age groups and in rehabilitation contexts (Song et al., 2012). Variability of practice is considered to accentuate task variations during learning such that, even though varied practice may produce poor performance during the acquisition phase, it is important for the development of the schemata, which are responsible for the assembly and improved retention and transfer of motor learning.

Consolidation of Procedural Knowledge and Sleep Benefit

While practice is essential for learning, further improvement of skill occurs after cessation of practice, which is referred to as consolidation. Such consolidation takes two forms. First, there is the 'off-line' improvement of skill, which occurs over time after training has ceased and following sleep. Notable improvements in perceptual or motor skill can occur following sleep, and such sleep-dependent benefit seems to be related to the percent or relative combinations of the different stages of sleep (Karni et al., 1995; Walker et al., 2002). Second, the skill and associated memory trace acquired through practice become stabilized and are less subject to decay or interference (Robertson, 2012). Experimental evidence suggests that consolidation of sequence knowledge and motor skill adaptation is more robust under conditions when initial skill learning is followed by a task that either engages 'e.g., word list learning' or inhibits (using inhibitory brain stimulation) the declarative system relative to when the declarative system is not disrupted or taken offline after learning (R.M. Brown and Robertson, 2007; Galea et al., 2010; Keisler and Shadmehr, 2010). These findings indicate off-line consolidation of procedural skill relies not only on the engagement of neuroplastic mechanisms,

but also on the disengagement of an interaction between declarative and procedural memory systems.

A study (Kantak et al., 2010) of the consolidation of knowledge following goal-directed skill learning of arm movements used inhibitory brain stimulation to interfere with the function of both the primary motor cortex (M1) and dorsolateral prefrontal cortex (DLPFC) following learning of the task with both randomized and constant practice schedules. Interestingly, disruption of the DLPFC-reduced consolidation of knowledge acquired following randomized but not constant practice, while interfering with M1-reduced consolidation of learning when the practice structure was constant but not when it was randomized. These findings demonstrate that the practice structure employed during learning has a direct impact on the networks recruited for subsequent consolidation. It appears that the goal-directed nature of the randomized schedule leads to the recruitment of more frontal cognitive networks, while constant practice leads to the engagement of motor associative regions with no requirement for the frontal lobes.

Procedural Memory and Retroactive and Proactive Interference

In contrast to interleaved practice of several tasks during training that can be associated with superior learning, performance of two procedural tasks in close temporal proximity can also result in various types of cross-task interference. Retroactive interference refers to the interference of a newly acquired task with performance of a previously learned task. There is evidence that similar to declarative memory, most forms of procedural learning are also susceptible to such retroactive interference effects, with these effects being reduced as the temporal interval between performance of the two tasks is increased (Robertson, 2012). For many years explicit memory was considered to be subject to 'proactive interference,' whereby the memory for most recently learned information can be compromised by previously learned material, whereas implicit memory was thought to be immune to this kind of proactive interference effect. However, more recently, evidence has emerged that proactive interference is not necessarily confined to explicit memory and occurrence of proactive interference effects has been documented for some procedural tasks such as word stem completion priming (Lustig and Hasher, 2001). In terms of long-term retention, well-learned motor skills, such as swimming, skiing or riding a bicycle, are maintained over time and are relatively resistant to forgetting over time.

Neural Substrates of Procedural Learning

The first evidence that procedural learning recruits different brain networks from those mediating declarative memory came from the results of some pioneering studies performed over several decades by Brenda Milner and Suzanne Corkin with an amnesic patient called Henry Molaison (HM) (Corkin, 2013). HM had a bicycle accident as a young child, and subsequently developed debilitating seizures. In 1953, at the age of 27, he underwent brain surgery for relief of his intractable epilepsy. The surgical procedure involved resection of the medial temporal lobe bilaterally. Following surgery HM was observed to have profound amnesia (i.e., impaired declarative memory) for events following his operation, as he could no longer encode newly learned declarative information into long-term memory. However, HM's memory for events before the surgery remained intact; furthermore, he was capable of learning new procedural skills. For example, in a study conducted by Milner (1962), HM acquired the new perceptual-motor skill of mirror tracing (drawing a figure, e.g., star shape by looking at its reflection in a mirror), despite having no conscious recollection of previous training episodes. In addition, HM was shown to have normal learning but little conscious recollection of the acquisition of other motor and cognitive and perceptual skill tasks such as pursuit rotor and bimanual tracking (Corkin, 1968).

Subsequently, it was shown that patients with Korsakoff syndrome with damage to diencephalic structures (mostly the mediodorsal nucleus of thalamus and the mamillary bodies) have severe anterograde amnesia, but also maintained a normal ability to learn cognitive skills, perceptual skills, and motor skills (Martone et al., 1984; Nissen et al., 1989; Saintcyr et al., 1988). Studies of amnesic patients with medial temporal lobe damage either due to lesions (Reber and Squire, 1994), Korsakoff syndrome (Nissen et al., 1989), or a combination of lesions and Korsakoff syndrome (Reber and Squire, 1998) showed normal learning on the SRT task, while verbal report of knowledge acquired during the training episode is impaired, indicating that explicit learning was dependent on the medial temporal lobe; while implicit motor sequence learning must involve regions of the brain other than the medial temporal lobe. It was further demonstrated that patients with dysfunction of the basal ganglia due to Parkinson's disease (PD) (Knowlton et al., 1996a; Saintcyr et al., 1988) or Huntington's disease (HD) (Knowlton et al., 1996a; Martone et al., 1984) showed the opposite pattern of results to amnesic patients as they had impaired procedural skill learning while being able to learn declaratively. This 'double dissociation' between declarative and procedural learning in amnesic patients and patients with PD and HD led to the general view that declarative and procedural learning are mediated by distinct and separable neural systems, and that while the cortico-limbic-diencephalic structures are the substrates for declarative learning, the striatum and its cortical projections support procedural learning nature (Squire, 2004). However, based on evidence from multiple sources, e.g., clinical patient studies and imaging, it has become clear that procedural learning is not mediated by a single unitary system and that the different forms of procedural learning are mediated by brain structures other than the striatum, for early review see Soliveri et al. (1992). In light of the heterogeneity of findings across groups with different neurodegenerative disorders across diverse tasks tapping procedural memory, Squire (1987) proposed a reformulation of procedural memory as "a collection of different abilities each dependent on its own specialised processing system … one therefore should not expect that a single lesion would affect all of procedural memory." Furthermore, in the intervening years, imaging has revealed that the hippocampus is engaged during procedural tasks such as motor sequence learning (e.g., Schendan et al., 2003), while under some circumstances, declarative tasks such as spatial navigation, considered to depend on the hippocampus, also recruit the striatum (e.g., Iaria et al., 2003).

Neural Substrates of Motor Skill Learning

Neuropsychological studies on patient groups with neurodegerative disorders and imaging have revealed that procedural learning does not depend on a single system but that different types of procedural learning are mediated by specific brain networks. Execution of the pursuit rotor task has been shown to be associated with a network of distributed regions including cortical, striatonigral, and cerebellar. However, learning on this task involves the primary motor cortex (M1), supplementary motor area (SMA), and thalamus (Grafton et al., 2001), suggesting engagement of the sensorimotor circuit between the putamen, premotor cortex, SMA, and M1. Not surprisingly, learning on a bimanual tracking task recruits similar regions to the pursuit rotor including the M1, posterior cingulate, putamen, and right anterior cerebellum (Puttemans et al., 2005). One study (Laforce and Doyon, 2001) showed that mirror tracing was not impaired in PD patients but was impaired in patients with cerebellar damage. These results indicate that in the mirror tracing task presentation of familiar but distorted visual information, which must be 'translated' before an accurate response can be made, necessitates cerebellar rather than striatal involvement. Furthermore, patients with PD (R.G. Brown et al., 2003; Deroost et al., 2006; Doyon et al., 1997; Jackson et al., 1995; Kelly et al., 2004; Muslimovic et al., 2007; Pascual-Leone et al., 1993; Stefanova et al., 2000; Werheid et al., 2003; Westwater et al., 1998; Wilkinson and Jahanshahi, 2007; Wilkinson et al., 2009) or HD (Knopman and Nissen, 1991) show impaired learning on the SRT, confirming that motor sequence learning is dependent on the basal ganglia and their cortical projections. The involvement of the fronto-striatal circuits, particularly the motor and associative circuits, has been confirmed by imaging studies, which have shown that motor sequence learning on the SRT is associated with activation of M1, SMA and premotor cortex, DLPFC, and the putamen and caudate (Grafton et al., 1995; Hazeltine et al., 1997; Poldrack et al., 2005; Schendan et al., 2003; Seidler et al., 2005).

With regard to motor skill learning, different fronto-striatal circuits have been implicated in different stages of learning (Graybiel, 2005; Hikosaka et al., 2002; Yin et al., 2009). Most recently, evidence from single-cell recording studies in mice indicates the dorsomendial striatum that is equivalent to the caudate in primates is involved in fast learning while the dorsolateral striatum – equivalent to the putamen in primates – is involved in slow automatized learning. This evidence suggests that in humans the associative circuit between the caudate and DPLFC and the sensorimotor circuit between the putamen and motor cortex are involved in fast and slow learning, respectively (Graybiel, 2005; Hikosaka et al., 2002; Yin et al., 2009).

Neural Substrates of Perceptual/Cognitive Procedural Skill Learning

Patients with PD (Knowlton et al., 1996a; Shohamy et al., 2004; Wilkinson et al., 2008; Witt et al., 2002) or HD (Knowlton et al., 1996a) are impaired at probabilistic classification learning on the WPT. However, imaging studies in healthy controls and PD patients have demonstrated involvement of both declarative and procedural networks in WPT learning, even though the time course of their recruitment during learning is different, and their activity is competitive (Aron et al., 2004; Foerde et al., 2006; Moody et al., 2004; Poldrack et al., 2001; Poldrack et al., 1999; Seger and Cincotta, 2006).

For other cognitive and perceptual procedural tasks, evidence indicates that they involve different networks. For example, a study of amnesic patients with medial temporal lobe damage showed they were impaired on an implicit conceptual memory priming task (Wang et al., 2010). Moreover, imaging evidence from healthy volunteers showed that implicit associative learning recruited the hippocampus rather than the basal ganglia (Degonda et al., 2005). So the role of the medial temporal lobe does not seem to be simply confined to declarative memory. Similarly, imaging evidence indicates that prism adaptation and mirror reading both recruit the superior temporal cortex and cerebellum (Luaute et al., 2009).

Other evidence indicates that the procedural-implicit/striatal versus declarative-explicit/medial temporal lobe distinction may be too simplistic. First, the idea these two memory systems are separable specifically on the basis of whether or not the learning is conscious in nature has been challenged (see Section The Question of Awareness below), as has the idea that nondeclarative procedural learning is the only form of skill learning dependent on the basal ganglia. For example, one study showed normal implicit SRT learning by patients with HD, while at the same time they were impaired at a modified SRT task, in which a sequence of target locations was explicitly learned by trial-and-error method (R.G. Brown et al., 2001). Another study found that both implicit and explicit sequence learning were impaired in PD (Wilkinson et al., 2009). Furthermore, similar to implicit sequence learning, the caudate, putamen, DLPFC, premotor cortex, and SMA are all activated during explicit sequence learning in healthy participants and are under activated in PD patients relative to controls (Carbon et al., 2003; Grafton et al., 1995; Jenkins et al., 1994; Jueptner et al., 1997; Lehericy et al., 2005; Nakamura et al., 2001; Schendan et al., 2003; Willingham et al., 2002). Second, it has been suggested that for some forms of procedural learning, the reason the basal ganglia are recruited is due to the fact that the task involves the processing of corrective feedback rather than because it is an implicit task per se (Holl et al., 2012; Shohamy et al., 2004; Wilkinson et al., 2008). Finally, and as mentioned above there is evidence that, rather than operating independently, the declarative and procedural systems interact in a dynamic manner (Foerde et al., 2006; Hartley and Burgess, 2005; Iaria et al., 2003; Myers et al., 2003; Sadeh et al., 2011).

The Question of Awareness

A core feature of some types of procedural learning is the concept that such learning is implicit and occurs without conscious awareness. For example, a great deal of research has been conducted on the question of whether knowledge acquired on the SRT is genuinely unconscious. Posttraining tests of awareness include asking participants to verbally report the sequence they learned. However, verbal report is not

sensitive to all of the conscious knowledge an individual may possess (Shanks and St John, 1994). Other more objective tests of awareness have been developed for the SRT such as free-generation and recognition tests. Some have proposed that the degree to which participants can control the generation of their sequence knowledge, either intentionally expressing or withholding it, is more relevant to understanding whether learning is genuinely unconscious. Destrebecqz and Cleeremans (2001) developed posttraining free generation tasks which participants performed under both 'inclusion' (express as much of the trained sequence as possible) and 'exclusion' (withhold production of the trained sequence) conditions. While Destrebecqz and Cleeremans' free generation under inclusion versus exclusion instructions data suggested that under some circumstances (e.g., speeded performance) learning on the SRT occurred with limited awareness, others (Wilkinson and Shanks, 2004) have not replicated their findings and questioned if learning on this task is ever truly implicit. Hence, the question of whether sequence learning can be implicit and whether genuinely implicit knowledge even exists is still debated.

Conclusions

The value of a procedural memory system is that once skill is acquired, performance can often proceed automatically without the need for allocation of significant attention. This liberates attention to be allocated to other urgent processes. For example, once the skill of driving a car has been acquired, a person can simultaneously drive and hold a conversation.

More recent evidence has highlighted the need for revision of the classic view of two independent memory systems: a declarative system mediated by the medial and diencephalic structures, and a procedural system based on the basal ganglia. First, instead of a single and unified procedural system based on the striatum, evidence across a range of different tasks suggests parallel and independent forms of procedural learning, only some of which may engage the striatum. Second, the view of two independent memory systems has been replaced with operation of two interactive memory systems that may become engaged at different stages of declarative and procedural learning.

Abstract

The nonequivalent group design is a quasiexperiment that draws comparisons among groups of participants who are assigned to different treatments in a nonrandom fashion. Selection differences are likely to bias the estimates of the treatment effects. Analysis strategies and design features for taking account of this bias are described. These analysis strategies and design features impose different assumptions about the nature of selection. Unfortunately, researchers will seldom have enough information to know which set of assumptions is correct in any given situation. In general, the recommended approach is to minimize the bias as much as possible by making the nonequivalent groups as similar as possible.

In nonequivalent group designs, comparisons are drawn between two or more groups of study participants with each group receiving a different treatment. The purpose, as in all quasiexperiments, is to assess the relative effectiveness of the different treatments. What distinguishes a nonequivalent group design from other designs is the manner in which the study participants are assigned to the different treatments. In a randomized experiment (*see* Random Assignment: Implementation in Complex Field Settings), participants are assigned to treatments at random. In a regression discontinuity design (*see* Regression Discontinuity Design), participants are assigned to treatments based on their value on an ordered quantitative variable. In a nonequivalent group design, participants are assigned to treatments in a nonrandom, nonquantitatively ordered manner. For example, a nonequivalent group design arises when participants self-select themselves into the different treatments, when an administrator assigns participants to different treatments, or when different treatments are implemented in different sites. In analyzing data from nonequivalent group designs, researchers must be concerned with biases that can arise because of the nonrandom assignment. The discussion describes the most widely used statistical analyses and design features for addressing these biases.

Threats to Internal Validity

Because the participants are not assigned to treatments at random, the treatment groups in a nonequivalent group design will differ, to some degree or other, even before the treatments are administered. Such differences among the treatment groups are called selection differences. In the nonequivalent group design, selection differences are a threat to internal validity (*see* Internal Validity) because they can bias the estimate of the treatment effect, that is, selection differences can cause posttreatment differences between the treatment groups, even if there are no treatment effects.

In addition to selection differences, other threats to internal validity can also arise in nonequivalent group designs. For example, Cook and Campbell (1979) list several additional threats to internal validity, including compensatory equalization of treatments, compensatory rivalry, resentful demoralization, diffusion or imitation of the treatment, and local history. Threats to validity that involve recognition that different participants receive different treatments, such as resentful demoralization, are likely to be more severe in randomized experiments than in nonequivalent group designs (Fetterman, 1982; Lam et al., 1994). On the other hand, threats such as local history will often be more severe in nonequivalent group designs than in randomized experiments. Although a variety of threats to internal validity can arise, the remainder of the present discussion will be concerned only with taking account of selection differences because it is that threat that most distinguishes nonequivalent group comparisons from other types of comparisons.

The Prototypic Nonequivalent Group Design

In the prototypic nonequivalent group design, only two treatments are compared: an experimental and a comparison treatment. In addition, the participants in each of these two treatment conditions are assessed at exactly two points in time, once before and once after the treatments are implemented. Differences between the two treatment groups on the posttreatment measure are then used to estimate the effects of the treatments and the pretreatment measure is used to take account of the effects of selection differences. If there were no pretreatment measure, the results would usually be uninterpretable because there would be no way to take account of the effects of selection differences.

Various statistical procedures have been proposed for taking account of the effects of selection differences, with the assistance of the pretreatment scores. The four most commonly used methods are described below. In general, all four of these procedures are most credible when the pretreatment measure is operationally identical to the posttreatment measure.

Each of the four analysis strategies imposes different assumptions about the nature of the selection differences. If the assumptions of a given procedure are correct, the resulting estimates of the treatment effects will be unbiased by selection differences. However, if the assumptions are incorrect the

estimates of treatment effects are likely to remain biased, perhaps severely so. Therefore, researchers must be diligent in choosing an analysis strategy whose underlying assumptions fit the circumstances at hand. Unfortunately, researchers will seldom, if ever, have enough information to know which set of assumptions is correct. As a consequence, researchers are advised to conduct multiple analyses that impose a range of plausible assumptions about the nature of selection differences. Even then, researchers will typically need to be cautious in interpreting the results from prototypic nonequivalent group designs.

Change-Score Analysis

In change-score analysis, the estimate of the treatment effect is the mean difference between the experimental and comparison groups in the amount of change that takes place from the pretreatment measure to the posttreatment measure. For this change from pretreatment to posttreatment to be meaningful, the pretreatment and posttreatment measures must be operationally identical. A change-score analysis can be implemented by calculating a pretreatment to posttreatment difference (i.e., a change score) for each individual and then performing a test of the mean difference between the treatment groups on the change scores (Donald and Lang, 2007). The same result can also be obtained using the pretreatment and posttreatment scores in a repeated-measures analysis of variance.

The underlying assumption in the change-score analysis is that the mean change from pretreatment to posttreatment will be the same in the two treatment groups, in the absence of a treatment effect. This assumption may or may not be correct. Sometimes treatment groups change at different rates so the gap between them either increases or decreases over time, even in the absence of a treatment effect. Such an outcome is called a selection-by-maturation interaction. For example, gaps in income often increase over time because the rich tend to get relatively richer. Patterns such as this can be accommodated in some cases by transforming the pretreatment and posttreatment measures to have equal variances (Judd and Kenny, 1981). In other circumstances, treatment groups change so that the gap between them decreases over time. For example, the gap would tend to decrease if individuals in one or both groups were selected for their extreme scores on the pretreatment measure and subsequent performances regressed back toward the mean. This is called a regression artifact (Campbell and Kenny, 1999).

Whether alternative explanations can account for the observed results sometimes depends on the pattern of the outcomes (Cook and Campbell, 1979). For example, when the experimental group starts out below the comparison group but ends up higher, the pattern of outcomes is called a crossover interaction. Such a pattern seldom can be plausibly explained as due to either a selection-by-maturation interaction or regression toward the mean. However, patterns that can be interpreted credibly are not always easy to produce in practice.

Matching or Blocking

In matching, each participant from the comparison group is paired with a participant from the experimental group so that they have the same or similar pretreatment scores (Rosenbaum and Rubin, 1985; Dehejia and Wahba, 2002). Participants who cannot be matched are discarded from the analysis. The effect of the treatment is then estimated by comparing the posttreatment scores in each matched pair (e.g., via a matched-pair *t* test). In blocking, the participants are matched in groups (or blocks) based on their pretreatment scores, and then comparisons are drawn between the posttreatment scores within each of the blocks (e.g., via a 'randomized' blocks analysis of variance).

The degree to which matching or blocking removes bias due to selection differences depends on several factors. First, bias reduction depends on how similar the participants are on the pretreatment measures within each pair or block (Cochran and Rubin, 1973). As the number of pretreatment measures increases, usually it is harder to form pairs or blocks in which the participants are similar on all the measures. This problem can be addressed by matching or blocking participants on the basis of propensity scores, which are single-variable aggregates of multiple pretreatment measures (Rosenbaum, 2002).

Second, bias will remain to the degree the pretreatment scores contain measurement error. Under some assumptions, measurement error can be taken into account by matching or blocking participants using pretreatment scores that are corrected for their degree of unreliability.

Third, bias reduction depends on the degree to which the pretreatment measures tap all the factors that influence the posttreatment scores and on which the treatment groups differ. For example, to the extent (1) the participants within each pair or block are not matched on, say, motivation, (2) the treatment groups differ in motivation, and (3) motivation influences the posttreatment scores, then matching or blocking will fail to control for the effects of all selection differences. Unfortunately, there is seldom any way to be sure that all the relevant selection differences have been assessed and included in the analysis. Often the best, though still fallible, way to assure that most of the relevant factors are taken into account is to use pretreatment measures that are operationally identical to the posttreatment measures.

Analysis of Covariance

Analysis of covariance (ANCOVA) is analogous to matching and blocking. The difference is that ANCOVA matches participants mathematically rather than by physically forming pairs or blocks of similar participants (Reichardt, 1979). By matching mathematically, ANCOVA avoids the problem of inexact matches that can arise when using pairs or blocks, but does so at the expense of having to impose assumptions about the shape of the regression surface between the pretreatment and posttreatment scores (Van Breukelen, 2006).

An analysis of covariance is accomplished by regressing the posttreatment scores on to both pretreatment measures and a dummy variable that indicates membership in the different treatment groups. The estimate of the treatment effect is the regression coefficient for the group-membership dummy variable. Although not as problematic for ANCOVA as for matching or blocking, having a large number of pretreatment measures can make the analysis difficult to implement, and this difficulty might again be reduced by using propensity scores.

Like matching or blocking, ANCOVA is susceptible to biases due to measurement error in the pretreatment scores. Analytic adjustments can be made in ANCOVA to address unreliability in the pretreatment scores (Sorbom, 1978). ANCOVA is also just as susceptible as matching or blocking to biases due to omitting pretreatment measures that influence the posttreatment scores and on which the treatment groups differ. Unless the pretreatment measures capture all of the selection differences that influence outcomes, the results of ANCOVA, like matching or blocking, are likely to remain biased.

Selection Modeling

In selection modeling (*see* Selection Bias, Statistics of), the posttreatment scores are regressed on to both pretreatment measures and a 'selection' variable that models the assignment of participants into the treatment groups. The estimate of the treatment effect is the regression coefficient for the selection variable in this regression equation (which will be called the 'outcome' regression equation).

The selection variable that appears in the outcome regression equation can be constructed in a variety of ways depending on the circumstances (Barnow et al., 1980). One way to construct the selection variable is to set it equal to the predicted scores from what will be called a 'selection' regression equation wherein a group-membership dummy variable is regressed linearly on to both the pretreatment measures that were used in the outcome regression equation and additional pretreatment measures that were not included in the outcome regression equation. The underlying assumption is that the unique pretreatment measures that are added to the selection regression equation are related to group assignment but do not themselves influence the posttreatment measures.

An alternative way to create the selection variable is to set it equal to the predicted scores when a group-membership dummy variable is regressed onto the pretreatment measures using probit or logistic regression. Using a probit or logistic, rather than a linear, regression produces a selection variable that is a nonlinear function of the pretreatment measures. The underlying assumption in this analysis is that the relationship between the pretreatment and posttreatment scores would be linear, in the absence of a treatment effect.

More Elaborate Nonequivalent Group Designs

A variety of design features are described below that can be added to the prototypic nonequivalent group design to improve the interpretability of the results (Shadish and Cook, 1999). The logic is to create a design where the pattern of results that would arise from a treatment effect is different from the pattern of results that would arise from selection differences (Reichardt, 2000).

Multiple Outcome Measures

The credibility of inferences from nonequivalent group comparisons can sometimes be increased by adding another outcome measure, often called a nonequivalent dependent variable (Cook and Campbell, 1979). Causal inference will be enhanced if selection differences have the same effects on both the original and additional outcome measures, but the effect of the treatment differs on the two measures (or vice versa). For example, in a study of a program to aid the homeless (Braucht et al., 1995), the primary intent of the treatment was to decrease substance abuse and only secondarily to improve other outcomes such as family relationships. In contrast, selection differences, such as differences in motivation to change one's lifestyle, should have had just as large an effect on family relationships as on substance abuse. That a large outcome difference appeared on measures of substance abuse but not on measures of family relationships increased the researchers' confidence that the positive results on substance abuse were due to the treatment, rather than to selection differences.

Multiple Comparison Groups

The credibility of inferences from nonequivalent group designs sometimes can be increased by using two comparison groups in the design rather than just one. For example, a design with two comparison groups allows the experimental group to be compared with each separately. This could strengthen confidence in a causal inference if the treatment were known, say, to have an effect in the same direction in both comparisons while the effects of selection differences were known to operate in opposite directions. In such a case, similar results in the two comparisons suggests the treatment, rather than selection differences, is responsible for the outcome.

Alternatively, additional comparison groups might be included in the design so that different comparison groups could be used to satisfy the assumptions of different statistical analyses or multiple comparison groups could be used to assess the plausibility of the assumptions of a given statistical analysis. For example, a change-score analysis could benefit greatly if, relative to the experimental group, one comparison group is initially inferior and the other initially superior on the pretreatment assessment. The most interpretable pattern of results would be where the mean changes from pretreatment to posttreatment were the same in the two comparison groups but different in the experimental group. Such an outcome would rule out both a selection-by-maturation interaction and regression toward the mean more credibly than would be possible with only a single comparison group.

Multiple Time Points

It can be useful to collect both pre- and posttreatment measures at additional time points. Pretreatment measures at additional time points can be used to improve the prediction of growth trajectories in the absence of the treatment. For example, suppose pretreatment measures are collected at both times 1 and 2, different treatment protocols are introduced at time 3, and posttreatment measures are collected at time 4. Then growth trajectories estimated using the time 1 and 2 measures can help distinguish between treatment effects and selection-by-maturation interactions. With even more pretreatment measures collected over time, researchers could also assess the plausibility of regression toward the mean. In either case, growth trajectories could be estimated using either mean level

analyses such as change-score models or individual level analyses such as latent growth curve models (McArdle, 1988; Muthén and Curran, 1997) (*see* Growth Curve Analysis) or hierarchical linear models (Bryk and Raudenbush, 1992).

Alternatively, pretreatment measures at times 1 and 2 could be analyzed as if they were a pretreatment and a hypothetical posttreatment measure. Because the different treatments were not introduced until later, such 'dry-run' analyses should produce null results except to the extent they are biased by selection differences or other threats to validity. In this way, the results of such analyses could be used to choose or modify statistical procedures so they are less likely to be biased by selection differences when used to analyze the actual pretreatment and posttreatment data (e.g., Wortman et al., 1978).

In a similar vein, posttreatment observations at additional time points sometimes can be used to distinguish between treatment effects and selection differences. For example, imagine that the effect of the treatment would increase over time while the effect of selection differences would remain constant or decrease over time. In such a case, a pattern of observed differences that increase over time would contribute to one's confidence that these differences are due to the treatment. For example, the conclusion that smoking causes cancer was strengthened when it was found that the rate of lung cancer in women smokers rose 20–30 years after smoking became prevalent in women, while the lung cancer rate in nonsmoking women remained relatively constant. The alternative explanation that genetic differences between smokers and nonsmokers was responsible for the observed association between cancer and smoking (because genes might produce both a liking for cigarettes and greater susceptibility to lung cancer) could not explain such an outcome, because genetic differences would be expected to be relatively stable over that 'short' a time period.

Variations in Amounts or Types of Treatments

Adding observations at additional time points or adding multiple comparison groups provides the opportunity to introduce repetitions of the same treatment, different amounts of the same treatment, or different types of treatments. For example, suppose the treatment could be introduced, removed, and then reintroduced to the experimental group and that observations could be collected at all the time points before and after these interventions for both the experimental and comparison groups. Further, suppose the effect of the treatment is short-lived (so the treatment's effects are not present when the treatment is removed) and that the effects of selection differences are constant over time. Then a pattern of outcome differences that varies over time in accord with the varying interventions could be strong evidence in favor a treatment effect.

Another possibility is the switching replication design (Cook and Campbell, 1979) where the treatment is administered to the experimental group at one point in time and then administered to the comparison group at a later point in time, with observations being collected on each group initially and after each of the treatment administrations. The premise of this design is that the difference between the groups in the effect of the treatment varies over the time periods because the administration of the treatment varies, but the effect of selection differences remains the same because the composition of the groups remains the same.

Another potential source of complex patterns with which to distinguish treatment from selection effects are designs in which groups of participants receive varying amounts of the treatment. For example, one set of the participants in the experimental group might receive the standard dose of a treatment while other sets of participants receive either half or twice the standard dose. The underlying premise of such designs is that different treatment doses produce systematically different outcomes (sometimes called the dose–response curve for the treatment), while the effects of selection differences would follow a different pattern.

The Benefits of Disaggregation

The preceding discussion describes potential benefits of additional outcome measures, comparison groups, time points, and treatments. Incorporating these design features often requires collecting additional data, but sometimes can be accomplished by disaggregating the available data. For example, sometimes it is possible to add a nonequivalent dependent variable by disaggregating the data from an outcome variable that consists of a battery of measures. Or a comparison group sometimes can be added by dividing what was initially a single comparison group into two groups. Or comparisons between different dosage levels of the treatment might be obtained by partitioning the experimental group according to the amount of treatment received. Even additional time points sometimes can be added to a design by partitioning data that initially were aggregated, say, at yearly time intervals, into data aggregated only at monthly intervals.

Minimizing Selection Differences

Researchers should try to implement designs and analyses that are most capable of taking account of selection differences in the specific situations at hand. Applying a complex statistical procedure to data from a prototypic nonequivalent group design may be appealing in theory, but a much simpler statistical analysis combined with a more elaborate design will often be more credible in practice.

However, regardless of the simplicity or elaborateness of the research design and statistical analysis, the credibility of a nonequivalent group comparison tends to increase when selection differences are made small and the treatment effects are made large. Random assignment tends to make selection difference small. In nonequivalent group designs, selection differences can often be minimized by using an assignment procedure that is as close to random as possible. For example, Langer and Rodin (1976) assessed the effects of a treatment by drawing comparisons across the clients on different floors of a nursing home. In this case, the assignment of clients to treatment conditions appeared to be quasirandom in that there were no obvious mechanisms by which different types of clients would be assigned systematically to different floors.

Often selection differences are smaller when the experimental and comparison groups are composed of individuals recruited from the same organization or locale (called internal

controls) than from different organizations or locales (called external controls). A special case of internal controls arises when the experimental and comparison groups are made up of earlier and later cohorts (Cook and Campbell, 1979). For example, the effect of a treatment that is given to college sophomores in a given year could be assessed by drawing a comparison with the performance of sophomores at that college from the prior year. Such a design is worth considering when the cohort of sophomores from the prior year is more similar to the treatment group than would be a contemporaneous comparison group of freshman or juniors from the same college or of sophomores from a different college.

Summary

Primarily because of biases due to selection differences and because of the difficulty in taking these biases into account, nonequivalent group designs generally produce less credible results than randomized experiments. Nonetheless, nonequivalent group designs are used widely because they can be far easier to implement than randomized experiments. Researchers should try to take account of the biasing effects of selection differences by the judicious combination of analysis strategies and design features. It is also advisable to minimize selection differences a priori so as to minimize one's reliance on either statistical procedures or design elaborations.

Nongovernmental Organizations: Anthropological and Historical Aspects

Julia Elyachar, School of Social Sciences, UC of Irvine, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews the brief history of the NGO, including its relation to development, neoliberalism, the United Nations, and mutual aid organizations. NGOs gather and render actionable forms of knowledge from diverse locations, at the interface of financial infrastructures and fields of organizational power. Like ethnography, NGOs render local forms of embodied knowledge explicit, quantifiable, and commensurate with knowledge in other locations of the globe. This has made them a popular if problematic location for fieldwork. As a flexible socio-technology, the NGO form interpolates global flows of knowledge, power, and finance.

Knowing and Working with NGOs

What are NGOs? This simple question has proven difficult to answer. Many social scientists write about NGOs. Many anthropologists in particular find professional employment in NGOs. NGOs are a common starting point for the signature research method of anthropology – fieldwork. Many things are confusing about NGOs. Perhaps the most confusing is how straight forward NGOs seem to be. The very name 'NGO' is a definition: An NGO is a nongovernmental organization. But that name/definition obscures as much as it explains. 'NGO' is neither a concept grounded in social or political theory, nor did it evolve out of critical engagements with classical social theory. NGO is not a translation of any particular 'native concept.' At the same time, something resembling NGOs exist everywhere. So do the local precedents for the NGO. Mutual aid societies across the (sometimes overlapping) Islamic majority world and the African continent have much in common with NGOs. So do the nineteenth-century Western charitable organizations aimed at reform and self-improvement of the poor in the West, and in the far reaches of empire at the turn of the twentieth century. NGOs look different in different places, depending on the nature of the state in which they are located and where they are active.

Social scientists encountered NGOs in the course of their research and began to write about them in the late 1980s. Influential reviews began to be published in the late 1990s (Fisher, 1997; Keck and Sikkink, 1998; Kearney, 1995; Mertz and Timmer, 2010). A next wave of research was presented in conference panels of the American Anthropological Association (AAA), organized by the Association of Political and Legal Anthropology in particular. By 2012, there was a robust body of published research on NGOs in social sciences, including anthropology. NGOs were being discussed within a wide range of social science disciplines, subfields, and an 'interest group' on NGOs in the AAA. Since NGOs are now everywhere, no area studies association specializes in their study.

NGOs are a kind of private voluntary organization (PVO). But not all PVOs are NGOs. Some NGOs are charitable organizations, but not all charitable organizations are NGOs. The organizing logic of NGOs is not profit, but NGOs are key intermediaries in global financial transfers. The organizing logic of NGOs is not formal politics, but NGOs are central to global political economy and the remaking of politics since the 1980s. NGOs appear in many shapes and forms. Some are linked to states, and some are linked to corporations. They can range from small local volunteer organizations to large international organizations with a professional staff. NGOs associated with states or corporations used to be seen as an aberration. The NGO was, in this first wave of research, assumed to be the organizational self-expression of 'the people.' But as the list of exceptional NGOs grew, it became harder to see them as exceptions. Overall, attempts to explain the NGO with recourse to another social science concept – be it civil society, neoliberalism, or antidevelopment – have proven insufficient. Recent writing on NGOs in anthropology has tended to be less normative in approach, and to focus more on what anthropology does best – analysis of tacit practices juxtaposed with analysis of programmatic statements.

Social scientists work with and on NGOs for different reasons. Some are pragmatic. Where it was once common for anthropologists to take 10 years to complete a degree that involved learning foreign languages and spending more than a year in the field, students are now under constraints to finish their PhD in 6 years. In the new climate, NGOs offer important benefits. English is the lingua franca of the NGO world. A student conducting fieldwork from an NGO need not invest heavily in language study. NGOs gather information about local conditions. That information is important to anthropologists and other social scientists for research. It is important to development agencies, international organizations, and corporations as well. Researchers who conduct fieldwork from NGOs can bypass immersion in the "imponderabilia of everyday life," to use the phrase made famous by anthropologist Branislow Malinowski, even while producing knowledge that is certifiable as 'local' and valuable for a number of ends. Furthermore, NGOs provide ethnographers with a ready-made set of introductions to informants. Entering the field via an NGO has implications for research outcomes that also need to be addressed. NGOs provide employment for an elite segment of educated youth throughout the global South. This leads to a growing congruence between the knowledge practices of social scientists studying NGOs and those working in NGOs (Elyachar, 2005; Riles, 2003). At the same time, to bypass the study of NGOs because they are not 'ethnographic' in the traditional sense would be absurd. The best ethnographic

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12214-7

research on NGOs situates them in a broader discursive and ethnographic field, and reveals their role in mediating other flows of meaning, value, power, and faith.

A (Very) Brief History of the NGO

The term 'nongovernmental organization' was formalized with the establishment of the United Nations (UN) in 1945. In the UN Charter, 'nongovernmental associations' were assigned 'consultative status' with the Economic and Social Council (ECOSOC). ECOSOC oversees about 70% of the resources of the entire UN system, including 14 specialized agencies, nine 'functional' commissions, and five regional commissions. The NGO branch services 3500 NGOs in consultative status with the ECOSOC, as well as "all other NGOs seeking to work with the UN" (http://csonet.org/).

And yet, few PVOs called themselves NGOs until the 1980s. NGOs were first studied in the field of development. Development is a discourse and a set of practices that organized relations between the former colonial powers, the US in its ascendency, and former colonies and territories of defeated empires. Before the 1980s, this went on via states and shifts in global financial flows are essential prehistory. From 1973 until the 1982 Latin American debt crisis, the US banking system channeled 'sovereign loans' to postcolonial states to carry out their development projects. This direct lending complemented lending through Bretton Woods institutions, in particular the World Bank. After the Latin American debt crisis in 1982, opinion about state-led development (as well as sovereign lending to Latin American countries) began to shift: postcolonial states began to be seen as 'corrupt.' These macro-level shifts in financial flows between global North and South are essential prehistory of the NGO. In this moment, 'communities' and 'social movements' appeared to be a better and nonoppressive framework through which to work for the improvement of life-chances of poor people. NGOs arose as an informal organizational vehicle to advance the aspirations of indigenous communities, social movements, or poor women.

By the 1990s, anthropologists began to critique NGOs as 'neoliberal' (Karim and Leve, 2001). The NGO form indeed overlaps with neoliberalism as a mode of governing in a number of ways. Neoliberalism is a constructivist project (Brown, 2003). The NGO has been one important agent of that construction, actively implanting new kinds of normative economic rationality in multiple spheres of life. Around the world, NGOs helped create new economic subjectivities of the dynamic 'entrepreneur' as opposed to class-based solidarity or citizenship (Elyachar, 2005; Brown, 2003). Indeed, neoliberalism provided the discursive terrain around which the organizational form of the NGO took shape. But as both neoliberalism and NGOs proliferated and transformed, it became untenable to explain one by way of the other.

The Rise of Civil Society

Three long-term (and related) transformations seem tied to the rise of NGOs in the 1980s: the appearance of civil society movements in eastern Europe and the Soviet Union, the collapse of the Soviet Union and the International Communist movement, and an interlinked set of phenomena glossed as globalization. 'Civil society' was the organizing concept of movements across eastern Europe in the 1980s that aimed at opening space for the 'social' outside the sway of the totalitarian state (Mastnak, 2005). Western scholars discovered, championed, and wrote about this movement, setting the stage for an uncritical view of 'civil society' as a space of freedom. The civil society movement was marked by the politics of antipolitics and a lack of theory of the state or economy. In contrast with the centrality of ideology and party rule under communism, the civil society movement stressed the rule of law and a legal rules-based approach (Mastnak, 2005).

The eastern Europe experience was a crucible in which development organizations and the US foreign policy establishment adopted civil society with religious zeal to champion in the 1990s across Latin America and Africa as well as the former communist world (Comaroff and Comaroff, 2000). The antipolitical and rules-based approach of the civil society movement was positioned in opposition to the 'totalitarian state.' The 'nonpolitical' nature of the civil society movement laid a perfect staging ground for the rise of the NGO. This pragmatic orientation took on different meanings after the fall of the Berlin Wall. In some places, the NGO became an excuse for the offloading of entire state institutions, as in some countries on the African continent (Ferguson and Gupta, 2007). At other places and times, the nonpolitical reputation of the NGO allowed political activists to carry out work that would have gotten them arrested were it conducted in the framework of (banned) political parties.

Critique of Development and Globalization

The rise of the NGO also coincided with the critique of development. A wide-ranging critique in the social sciences in the 1980s pointed to the oppressive power relations inherent to the very practice and notion of development. While development had once seemed to be a scientific approach to improving the quality of life for the populations of newly independent states, the critique of development argued that development was actually detrimental to local populations (Elyachar, 2012). This approach went much further than criticism of a particular development approach. Rather, it pointed to oppressive power relations inherent to development as a whole. The critique of development was implicitly a critique of the state as well, since the state was the primary vehicle through which development was effected and carried out together with interstate post-World War II institutions such as the World Bank. Social movements and NGOs came to seem like an alternative to development. NGOs could be a vehicle for 'globalization from below' (Appadurai, 2000) and a potential site for the generation of alternative forms of knowledge and power that could counter the weight of 'the state–capital nexus' (Appadurai, 2000). The notion of 'empowerment' that had begun in the women's movement shifted into development world, and NGOs became central to any plan aimed at empowerment of women and increasing their participation in development and economic growth.

Research burgeoned into apparent alternatives to state-led development: NGOs, social movements, and the informal economy. Traditional approaches to development were overthrown. 'The people' were no longer in need of development. Rather, the developed world needed to learn from backward peoples and their cultural practices. Poor peoples' social networks and their traditional cultural practices would be something to learn from instead. They were a gold mine for the 'social capital' essential for a well-functioning market society. The 'antiglobalization movement' of this period was also deeply critical of the state and the state-led development. NGOs found champions here as well. NGOs represented 'the people,' free of the state. This focus on 'the people' was part of a broader transformation in the nature of political life and public policy (Clarke, 2010). All of these efforts came together in the new microenterprise and microfinance movement, which was channeled through NGOs. Access to credit would set the poor and their entrepreneurial capacities free. Access to credit would tap new sources of economic growth for the economy as a whole. Over the next two decades, this approach to microlending moved out of the incubator of NGOs and into mainstream financial institutions (Roy, 2012).

The Left, Knowledge, and Communications Infrastructures

The end of the Soviet Union in 1991 is also linked to the rise of the NGO. Many leftist organizations, political movements, and solidarity movements around the world collapsed in the early 1990s. Solidarity movements in the West were essential to the mobilization of funding flows to liberation movements in the global South – in Latin America and Africa in particular. Those financial flows were not huge. But in retrospect we can see how they created channels for transmission of information in one direction and finance in the other. NGOs regularized this communicative and financial infrastructure that had been implicit in the original 'consultative role' of the NGO in the 1940s.

Across the third world, activists in local liberation movements shifted into NGO work, with a widespread 'NGO-ification' of politics. Those who might have been part of political movements in the 1970s found employment opportunities in NGOs instead. Solidarity workers in the global North moved into NGO work as well. Solidarity movements had relayed remarkably accurate and valuable information about conditions on the ground in battleground countries of the Cold War in Central and Latin America through the 1980s. In Latin America, NGOs built on former communications infrastructures developed by solidarity movements, and expanded into new communications technologies. Activists in remote locations in the 1980s had taught local NGO members how to access the Internet, and how to patch into telecommunications networks when infrastructure was not otherwise available. All of this helped create a new communications infrastructure across the global South of which NGOs were an essential part. This helped lay the building blocks for a number of trends to come, ranging from microenterprise, microlending, women's empowerment, mobile banking, and bottom of the pyramid (BOP) corporate planning.

Warfare, Humanitarianism, and Human Rights

The NGO began as a part of interstate warfare and its containment, attending to the suffering of ordinary soldiers on the battlefield, as told in histories of the Red Cross and humanitarianism (Bornstein and Redfield, 2010). It came into legal existence with the establishment of the UN at the end of World War II. The NGO came into its own toward the end of the Cold War with the rise of the civil society movement in eastern Europe. The end of the Cold War with the collapse of the Soviet Union set the stage for the proliferation of NGOs, as we saw in the wake of the US invasion of Afghanistan and Iraq. NGOs have been popping up like mushrooms in the wake of conflict situations ever since. NGOs poured into Afghanistan together with the US Army, bidding up the price of labor, supplies, and property, and distorting local economies as they carried out their missions for good. In the process, links were deepened between NGOs and the corporate world, via the military (Nordstrom, 2004). Recent work on NGOs in the aftermath of conflict also looks at different ways of doing good (Bornstein, 2012) and humanitarianism (Fassin, 2011). In the context of NGOs, actions carried out by individuals in NGOs become a form of moral action linked to visions of a greater good in the future (Bornstein and Redfield, 2010), or a modality of 'killing with kindness' (Schuller, 2012).

Human rights NGOs have been the most directly political of NGOs in many countries and have mediated transnational human rights movements and forms of local activism (Merry, 2006). They have gathered information about human rights violations in many countries of the global South since the 1990s (Abdulrahman, 2005; Willen, 2012). Human rights NGOs have often had a contentious relationship with the states in which they are located. In Egypt, for example, human rights NGOs were often accused by the Mubarak regime of being agents of the United States and the West. (Such accusations are made in many countries where the state has politics opposed to the United States.) Information gathered by Egyptian NGOs about police brutality and torture in prisons under Hosni Mubarak played an important role in creating international legitimacy for the overthrow of the Mubarak regime. Once in power, the new government led by Mohamed el-Mursi prosecuted some of those NGOs in turn. The link between anthropology and human rights has provoked research in all parts of the world where anthropologists work, and leads to theoretical reconsiderations as well (Willen, 2012).

The Religion of NGOs

Institutionalized forms of charity and giving can also be found in all religious traditions. The story of the transformation of indigenous forms of giving and regulating giving into something recognizable as an NGO is particularly striking in the case of religious NGOs. NGOs, like 'civil society,' were assumed in the 1980s to be 'secular.' The NGO as the building block of secular civil society was taken up with religious fervor in the Middle East. NGOs would counter 'Islamic fundamentalism' through the strengthening of civil society and its economic incarnation: the informal economy and microenterprise. At the same time, Islamist political parties, movements, and

associations were providing aid and succor of the kind associated with the NGO. Social development and charitable initiatives are central modalities of ethical being in the world. Such sustained practices of doing good and providing social and development services filled gaping holes in the provision of social services.

In the case of Israel/Palestine, Islamist parties began to fill some of the stark needs of an actively 'de-developed society' (Roy, 1999). There, too, with the decline of the left and its own solidarity movements and self-help initiatives, Islamist movements filled in the gap. These practices that in substance so resembled those of NGOs were adamantly kept out of the main narrative of 'development,' which was assumed to be 'secular' despite the roots of development in Christian theology (Elyachar, 2012). Islamist forms of 'doing good' were often called 'terrorist' after 11 September 2001 (de Goede, 2012).

Associational life is nothing new in today's Middle East (Abdulrahman, 2005; Atia, 2011). Systematized forms of giving, not to mention formal legal institutions such as *waqf*, are recorded in *hadith* of the Prophet Muhammad and are a central part of Islamic history (Atia, 2011). The same is true of Jewish communal institutions, which have always organized to support their religious brethren in far away places, sending help and succor across the stretches of empire and ocean. The establishment of the Jewish National Fund (JNF) in 1901 as an entity to gather and channel resources for Jews through and around a state defined as both Jewish and democratic has intriguing hallmarks of a vast NGO. At the same time, in a state defined as both democratic and Jewish, NGOs organized to provide development assistance to Palestinian citizens building on the earlier secular language associated with the NGO are targeted as a security threat. Research on NGOs self-identified as Christian has also been increasingly important, starting with Bornstein's book on Protestant NGOs in Africa (Bornstein, 2005).

Microcredit has been an interesting terrain bringing together the NGO with ethical subjectivities long associated in the research with 'neoliberalism' but now taking on explicitly Christian or Islamic orientations. Especially in the wake of the Arab Spring, Islamist political parties have adopted social technologies of microcredit and microlending that were once associated with the Mubarak government in Egypt. 'Islamic NGOs' are being recognized and cultivated as partners for global financial flows (Atia, 2011). They are becoming part of a global political and financial order. This could be noted, for example, in an article in *The Financial Times* in 2012 about the work of Hernando de Soto, champion of the microenterprise and entrepreneurial self-help capitalism, with the Muslim Brotherhood government in Egypt.

BOP, Social Business, and NGOs

In recent years, the NGO has also moved into the heart of the corporate world. The notion of a corporate NGO seems a misnomer. Nevertheless, as written in the World Association of NGOs' (WANGO) *NGO Handbook*, the NGO is nonprofit as well as nonstate. But local knowledge has become increasingly important in the corporate world, and as 'social goals' become increasingly integrated into mission statements, the import of the NGO – and ethnography – into the corporate world has become evident. Like ethnography, NGOs render explicit cultural practices that were once known only to insiders. As increasingly important mediators of global financial flows, NGOs are key nodes of translation of culture into economic value (Elyachar, 2005). They render explicit tacit practices in particular locations and render them commensurable in a global order of political and financial arrangements. Given the centrality of 'knowledge' as a category in the corporate world in the past 30 years, and the growing importance of poverty markets (Roy, 2012), it should not surprise us to see the pervasive spread of the NGO in the for-profit world.

This appearance of the NGO in the corporate world is linked to the rise of the movement for 'corporate social responsibility' (CSR) (Browne and Milgram, 2009). The rise of CSR in the corporate world drew on another concept of the 'stakeholder' in management theory. Others besides direct shareholders of a company are also affected indirectly by its actions. Their voices also need to be heard. The management world began to discuss unintended consequences or 'externalities' outside the range of economic theory or measurement. Here, the consultative role for the NGO outlined in the UN charter took on a new function, in an area unthinkable when the UN was founded: the world of the for-profit corporations. In later theories of the BOP, social value was moved to the forefront of corporate strategic planning, rather than being tacked on at the end. As argued in the seminal work of Prahalad, "Marrying the local knowledge of the NGO with the global reach of the multinational firm" could create new solutions for global problems even as it creates new sources of profit for MNCs (Prahalad, 2004).

In Prahalad's formulation, NGOs became incubators for business models, "lead experimenters in BOP markets" (Prahalad, 2004: 56). NGOs could help MNCs understand not only what poor people wanted as consumers, but also learn to take advantage of the incipient infrastructures poor people had built without compensation or help from the state. The NGO would be a translator and conveyor belt of knowledge from the BOP to the MNC.

Knowledge and Action Research: The Pragmatics of NGOs

Conceptual and epistemological overlaps among management theory, theories of knowledge in private firms, and NGOs are a newer area of interest. One framework to analyze those overlaps is through the prism of 'action research.' This overlap can be seen in how NGOs in all spheres of their work have implemented and participated in projects to institute best practices and create actionable research in their field of interest. Future research will need to trace the concepts used by NGOs and follow their shared genealogies in the fields of economic theory, organizational management, practice theory, and critical theory.

Research on the anthropological aspects of NGOs can draw on organizational theory, management theory, and theory of knowledge and information. It would also be fruitful to explore a number of other related topics: the role of pragmatism in relation to NGOs, how NGOs function as a mechanism of valuation, and how NGOs function as a devise for rending the tacit visible and for rendering apparently incommensurable

qualities commensurable as quantities. For this kind of work, we will need to take a classic anthropological take on such matters: study what NGOs say they do, study what they actually do, and try to get a grasp on the 'imponderabilia of everyday life' that make them tick, to return to Malinowski's term for the object of anthropological knowledge in fieldwork among natives. In the NGO as well, we need to pay more attention to the mundane, everyday worlds of NGOs in action and on the ground.

It will likely prove important to return to the original role of the NGO in its foundational movement of the Bretton Woods system and the UN: gathering and rendering actionable forms of knowledge from diverse locations, at the interface of complex systems regulating financial flows and structures of organizational power. NGOs are a central part of the financial and political order put into place at Bretton Woods together with the UN. That moment reorganized systems of finance, power, and international order. The origin of the NGO is located at this global nexus of violence, finance, and information flows. This peculiar location, I want to suggest, may just be what makes the NGO an NGO.

At the same time, there may be good reasons why we still lack a theory of NGOs. So many things constitute a referent to 'NGO' that any concept potentially delimiting them can end up being negative (not the state), vague (organizations to do good), or normative. The NGO is associated with many things, but is an expression of no one of them. NGOs might best be understood as a type of organization that arose concomitant with a discourse of 'neoliberalism,' and came to function well as a flexible socio-technology interpolating global flows of knowledge, power, and finance.

Social science research into NGOs has tended to move between two tendencies. One approach has attempted to pinpoint the true nature or essence of the NGO, in all of its variable locations. Another approach has documented the specificity of what particular types of NGOs do in one particular location. Neither approach can suffice. Like ethnography, NGOs render local forms of tacit embodied knowledge explicit, quantifiable, and commensurate with knowledge in other locations of the globe. The NGO now lies at the nexus of violence, finance, and information flows the world over. The myriad ways in which they do so could not have been envisioned by those who established the NGO together with the UN at the end of World War II.

Non-Heterosexual British Asian Men: Social Representations, Identity and Social Relations

Rusi Jaspal, De Montfort University, Leicester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores social representations, identity, and social relations among nonheterosexual British Asian men. After an overview of two relevant theories from social psychology – identity process theory and social representations theory, the article outlines dominant social representations of sexuality that inform individuals' meaning-making, the impact of these representations for identity processes, how individuals cope with potential threats to identity, and the development and management of social relations. It is argued that being Asian and gay can result in threatened identity, leading to low psychological well-being and negative interpersonal relations.

Introduction

In the Western world, the social, political, and legal positions of nonheterosexual individuals have greatly improved, leading to greater tolerance and acceptance at a societal level. Yet, nonheterosexual ethnic and religious minority individuals can continue to face discrimination from within their ethnic and religious communities (Yip, 2004). Stigma can result in decreased willingness to 'come out' and perceived conflict between sexual and ethnoreligious identities (Jaspal and Siraj, 2011). Identity conflict can lead to a variety of negative social and psychological outcomes – the experience of negative emotions, low psychological well-being, and social isolation. This article explores identity, social representations, and social relations among one such ethnoreligious minority group in the UK context – nonheterosexual British Indian and British Pakistani men. Here, the focus is on nonheterosexual men, rather than women, because most previous research has concentrated on the identities, experiences, and relationships of men.

British Asians: An Overview

The term 'British Asian' denotes a superordinate ethnoracial category, used typically to refer to individuals of Indian, Pakistani, or Bangladeshi descent. At the time of the 2011 UK Census, (http://www.ons.gov.uk/ons/guide-method/census/2011/census-data/index.html) there were 2 984 670 individuals of South Asian descent resident in England and Wales. Within this superordinate category, Indians were the largest group (1 412 958); Pakistanis the second largest (1 124 511); Bangladeshis the third (447 201). British Asians constitute over 50% of the non-White population and are therefore the largest visible ethnic minority group in the country.

The sociodemographic makeup of British Asians is diverse and complex. The overwhelming majority of British Pakistanis are practicing Muslims, and most British Indians are, at least, nominally Hindu or Sikh (Ghuman, 2003). There have been various waves of immigration to the United Kingdom from the Indian subcontinent and therefore this is a demographically diverse group. Despite the sociodemographic variation, what most of the Asian immigrants shared was their socialization in a largely collectivist culture, which attached importance to kinship ('biraderi') and honor ('izzat'). These cultural tenets have remained powerful in the British Asian community (Ghuman, 2003), and in many cases, there remains a preoccupation among Asian parents that their children should be 'shielded' from the perceived immorality of elements of British/Western culture. Although there is little research into attitudes toward homosexuality among first-generation Asian immigrants, there is some evidence that this may be regarded in terms of a 'Western disease' that has 'infected' the Asian community (see Yip, 2007). Against this backdrop, this article examines and compares how men from the largest two nonheterosexual groups, British Indian and British Pakistani, construct identity and manage social representations and social relations.

Terminology

Various terms are used in academic work on sexuality. Terms such as 'gay,' 'lesbian,' and 'bisexual' are sometimes uncritically applied to research participants, despite the possibility that individuals themselves may deny that they are accurate descriptors of their sexual identity. Sexual self-definition depends on dominant social representations of sexual identity categories – what does it mean to be 'gay'? What are the cultural images of a 'typical' gay person? Where am I located in relation to these images? Constructivist approaches to sexuality emphasize fluidity in processes of self-categorization and self-definition (Seidman, 2003). Moreover, sexual self-definition can fluctuate throughout the life span – some individuals may initially view themselves as 'straight,' later concede that they may be 'bicurious,' and finally accept that they are actually 'gay.' As individuals encounter social representations of sexual identity categories, they may become more or less willing to embrace them. Thus, researchers should ensure that their terms capture potential fluidity in sexual self-identification.

In this article, the term 'nonheterosexual' is used. It has proven to be useful in research with ethnic and religious minority individuals, given that it embraces the plethora of sexual identity labels that individuals tend to use in contrast to 'heterosexual' (Yip, 2004). Moreover, it does not prioritize

any particular label (e.g., gay), which some individuals may find constraining and as inaccurately reflecting their sexual identity.

Theoretical Framework

In examining the construction and maintenance of identity, social representations, and social relations among nonheterosexual British Asian men, two theories from social psychology – identity process theory and social representations theory – have proven to be particularly insightful.

Identity Process Theory

Identity process theory (Breakwell, 1986; Jaspal and Breakwell, 2014) has provided a useful heuristic lens for understanding the construction and management of identity among nonheterosexual British Asian men. The theory integrates identity construction, threat, and coping, while synthesizing the social and psychological levels of analysis. Identity process theory proposes that identity construction is regulated by two universal processes, namely, (1) assimilation–accommodation and (2) evaluation. The assimilation–accommodation process refers to the absorption of new information in the identity structure (e.g., accepting that one is gay) and to the adjustment that takes places for it to become part of the structure (e.g., accepting that one is gay and therefore questioning one's membership in one's religious group). The evaluation process confers meaning and value upon the contents of identity (e.g., viewing one's sexuality positively).

These processes function to create specific desirable end-states for identity, namely, 'identity principles.' Identity processes are guided by the following principles: (1) continuity across time and situation (continuity), (2) uniqueness or distinctiveness from others (distinctiveness), (3) competence and control (self-efficacy), (4) personal and social worth (self-esteem), (5) inclusion and acceptance in groups (belonging), (6) significance and purpose (meaning), and (7) compatibility and coherence between interconnected identities (psychological coherence). Only the first four principles are consensually accepted in identity process theory – the latter three have been proposed by other researchers (Jaspal and Breakwell, 2014). The theory suggests that when identity processes cannot, for whatever reason, comply with psychologically salient principles, identity is threatened and the individual will engage in strategies to cope with the threat. A coping strategy is defined as "any activity, in thought or deed, which has as its goal the removal or modification of a threat to identity" (Breakwell, 1986: p. 78).

Coping functions at three levels: (1) intrapsychic, (2) interpersonal, and (3) intergroup. Intrapsychic strategies include inter alia denial and reconceptualization. Interpersonal strategies are those that rely on "changing relationships with others in order to cope with threat" such as self-isolation (Breakwell, 1986: p. 109). Intergroup strategies make use of intergroup dynamics in order to salvage identity and include making strategic use of multiple group memberships and actively seeking group support through social networks or consciousness raising/self-help groups.

Social Representations Theory

Social representations theory explains the development and dissemination of social knowledge. A social representation is defined as a system of values, ideas, and practices regarding a given social object, which facilitates communication and behavior (Moscovici, 1988). Social representations are context specific and create what one might call a shared social reality in which thinking and discussion regarding issues like sexuality can take place.

Moscovici (1988) outlines two processes that give rise to social representations, namely, (1) anchoring and (2) objectification. Anchoring refers to the process of making something unfamiliar understandable by linking it to something familiar. For instance, Jaspal and Siraj (2011) have found that nonheterosexual British Pakistani men may anchor homosexuality to 'decadent British culture,' which can provide an explanation for their sexual orientation. Objectification is the process whereby unfamiliar and abstract objects are transformed into concrete and 'objective' commonsense realities. The use of metaphor is one example of objectification.

Identity process theory and social representations theory share some common ground (Breakwell, 2014). Identity process theory acknowledges the importance of social representations in determining identity content, and the salience of identity principles in a given social context. Conversely, social representations may be embraced or resisted by individuals in order to provide feelings of self-esteem, continuity, and so on.

Identity and Sexuality: Managing Social Representations

Nonheterosexual British Asian men can experience identity threat as a result of exposure to negative and stigmatizing social representations of their sexuality, which in turn inform their own perceptions.

Sources of Social Representation

Nonheterosexual British Asian men constitute a diverse group. It has been argued that British Pakistanis tend to lack social capital, are less 'integrated' in British society and more ethnically and religiously 'insular' (Robinson, 2009). Conversely, British Indians are said to be relatively integrated in British society and to have access to a range of social group memberships – national and ethnic (Jaspal, 2011). Therefore, British Indians may be exposed to a wider range of social representations associated with these memberships. While the ethnoreligious in-group disseminates negative, stigmatizing representations of homosexuality, the sexual in-group (i.e., other nonheterosexual individuals) may be a source of positive representations. Conversely, nonheterosexual British Pakistani men may be more systematically exposed to negative and stigmatizing accounts of homosexuality, which are associated with their primary (ethnoreligious) group membership.

The availability of a variety of representations (associated with distinct group memberships) potentially provides individuals with opportunities to make strategic decisions about how they 'use' these representations. They may accept those representations that have favorable outcomes for identity processes while rejecting those leading to threat (Breakwell, 2014).

Sexuality: Behavior or Identity?

In general, being gay is defined in the West not only in terms of sexual behavior but also in terms of desire, lifestyle, culture, gender, politics, and identity. In short, being gay is frequently construed as an aspect of who one is. Conversely, in South Asian (and many other non-Western) cultures, men may indeed engage in homosexual acts but eschew self-categorization as gay – thus, it is not regarded as an aspect of one's identity (Murray and Roscoe, 1997).

Some nonheterosexual British Asian men may themselves eschew sexual self-categorization by describing their sexuality in behavioral terms, rather than as an identity (i.e., 'doing gay things rather than being gay'). This can have psychological advantages in the short term at least. The first concerns the perceived scope for changing one's sexual orientation. While the individual may view their identity as being static and resistant to change, they usually regard behavior as mutable and transient. Accordingly, some individuals may come to view their sexual orientation as a 'bad habit' rather than an identity (Jaspal and Cinnirella, 2010). The second advantage concerns the perceived 'origins' of homosexuality. Individuals who perceive their sexual orientation as a behavior may attribute their 'gay behavior' externally to their social surroundings. In one study, British Pakistani gay participants attributed their sexual orientation to the presence of 'gay culture' in 'British culture' (Jaspal and Cinnirella, 2010). The assertion was that something inherent to the sociocultural context of Britain had induced gay behavior.

Encountering Nonheterosexuality

Many nonheterosexual British Asian men believe that their ethnoreligious communities regard homosexuality as 'wrong' and, in some cases, 'sinful' (Yip, 2004). This perception seems to be reinforced by the negative, stigmatizing terms that are commonly used to denote homosexuality or gay people in individuals' heritage languages (Jaspal and Siraj, 2011). These terms are often derogatory and make reference to anal intercourse. Thus, sexualized terms, which are employed primarily as abusive remarks, can come to dominate thinking among nonheterosexual people, thereby encouraging a negative evaluation of homosexuality.

Research shows that individuals draw upon their previous encounters with the topic of homosexuality (involving their ethnoreligious in-group) in order to gauge potential reactions to their sexual orientation. In April 2009, the long-running popular British television soap opera *Eastenders* introduced a controversial storyline concerning a British Pakistani gay man, Syed Massoud. The storyline culminated in a dramatic and explosive public 'outing' of the character who was subsequently ostracized from both his family and ethnoreligious circles. Themes of family breakdown, depression, verbal and physical abuse, and suicide dominated Syed's coming out story. For some nonheterosexual British Asians, this storyline provided insight into what sexual self-disclosure might be like (Jaspal, 2010). Identification with the character and his plight appeared to dissuade individuals from ever coming out themselves. For some individuals, the storyline seemed to confirm and reinforce the perception that the ethnoreligious in-group is homophobic and will never accept homosexuality. This could create feelings of fear and anxiety about the future and prospect of coming out (Jaspal and Siraj, 2011).

There is an acute awareness of social representations of what it means to be a 'genuine' ethnoreligious in-group member, such as the importance of 'izzat' (honor) within family and ethnoreligious circles (Bradby, 2006). An essential tenet of maintaining family 'izzat' is the fulfillment of the ethnocultural expectation of marriage. However, it has been found that the expectation of marriage can be construed as a threat by nonheterosexual British Asians (Jaspal, 2012b). While the prospect of marriage may be avoided and suppressed in early adulthood, the completion of one's education seems to serve as a cultural cue for the prospect of marriage to reemerge. Conversely, a contravention of social representations concerning sexuality and marriage may be regarded as a threat to 'izzat' and lead to negative social and psychological outcomes. Individuals have reported fear of physical abuse from ethnic in-group members (and sometimes from family members). These fears are grounded in knowledge of 'honor crimes,' that is, psychological and/or physical abuse in the name of family honor.

Identity: Threat and Coping

Nonheterosexual British Asians may face 'hyperthreats,' that is, threats to several principles of identity. The following principles of identity seem particularly susceptible: (1) self-esteem, (2) belonging, (3) distinctiveness, (4) psychological coherence, and (5) continuity.

Self-Esteem

Homophobia and self-esteem are negatively correlated for gay men (Dupras, 1994). Individuals express acute awareness of the negative, stigmatizing social representations of homosexuality, which construct it as an abnormality or deliberate subversion, although the impact of this varies by cultural group. As observed above, many British Indian men seem to be able to overcome the social stigma associated with homosexuality through self-exposure to positive representations. In this case, self-esteem may be less susceptible to threat – individuals may in fact come to view their sexuality positively. However, in ethnoreligious contexts, individuals may be reminded that homosexuality is culturally unacceptable, due to the overt social stigma appended to this identity element. Furthermore, even among those men who have disclosed their sexuality to others, there may be a 'silencing' of homosexuality. Both overt condemnation of homosexuality and the more covert act of 'silencing' it can make it difficult for individuals to derive a positive self-conception on the basis of their sexuality – it is represented as something to be ashamed of. It threatens self-esteem only in those contexts in which social stigma acquires salience. Conversely, many nonheterosexual British Pakistani men, who tend to have less social capital, may themselves continue to evaluate their gay identity negatively. This negative evaluation of homosexuality at the psychological level can lead to a persistent threat to self-esteem.

Belonging

The perceived possibility of otherization and ostracization from their family and ethnoreligious circles – two valued group memberships – renders the belonging principle susceptible to threat. Exposure to negative representations can engender the belief that individuals will be excluded from relevant in-groups. Identity process theory argues that individuals will make use of their multiple social group memberships in order to safeguard identity. Accordingly, British Indians who decide to disclose their sexual identity to parents, family, and friends may attempt to derive feelings of acceptance and inclusion from alternative group memberships – by redefining themselves as 'primarily British' or as 'a gay man' (Jaspal, 2012b). In other words, their alternative group memberships (in this case, national and sexual, respectively) can acquire salience, becoming alternative sources of belonging when the ethnic/religious groups no longer satisfy the principle. However, this may be less of an option for British Pakistanis, many of whom have less social capital and may not have access to alternative group memberships.

Distinctiveness

Although a sexual minority identity is clearly one possible means of deriving feelings of distinctiveness from relevant others, it is likely that neither the level of distinctiveness nor the balance between distinctiveness and belonging will be satisfactory. Indeed, 'excessive' distinctiveness can be threatening for identity, since this can result in ostracization and exclusion. Moreover, distinctiveness that threatens self-esteem is unlikely to be beneficial for identity.

Distinctiveness can be threatened at another level. Nonheterosexual British Asian men generally express awareness of negative representations of homosexuality within their ethnoreligious in-group. In previous research, individuals have expressed fear of being 'homogenized' with 'typical' gay people with whom many perceive no affinity, solidarity, or 'oneness' (Jaspal and Cinnirella, 2010). There is evidence that many nonheterosexual British Asians have themselves internalized negative, stigmatizing representations of gay people – viewing them as 'camp,' 'flamboyant,' and 'too open' – from which they wish to distance themselves. The perceived possibility of being homogenized with 'typical' gay people may also result in threats to the distinctiveness principle. One means of protecting distinctiveness may be to avoid ever coming out (Jaspal and Siraj, 2011).

Psychological Coherence

In much recent research, the crux of the debate has been the extent to which sexual and ethnoreligious identities are subjectively perceived as compatible and coherent. Among British Pakistanis, the psychological coherence principle seems to be chronically threatened as a result of being gay and Muslim. Many individuals view the norms, values, and practices perceived to be associated with either identity as being in conflict. Among British Pakistani gay men, the perception that Muslim and gay identities are incompatible and incoherent can cause individuals to question their Muslimness, and to experience negative emotions such as shame, guilt, fear, and anger (Jaspal, 2012a). While British Pakistani gay men generally evaluate their Muslim identity positively and construct this identity as 'core,' they tend to evaluate their sexual identity negatively. Although the threat is often chronic, this asymmetry in identity evaluation can help to safeguard psychological coherence.

Conversely, there is little evidence that British Indian gay men experience threats to the psychological coherence principle. Unlike Islam, neither Sikhism nor Hinduism is particularly vocal on homosexuality. Thus, sexual and religious identities tend not to be 'interconnected' in the minds of individuals – they are simply not viewed as being relevant to one another (Amiot and Jaspal, 2014). For British Indians, psychological coherence may well be threatened during the early stages of sexual identity development, but does not seem to persist in the later stages of identity development. British Indians seem more able than British Pakistanis to reconstrue what it means to be gay and Asian – ethnic and sexual identities can cease to be 'interconnected' and, thus, psychological coherence becomes a nonissue.

Continuity

While psychological coherence is concerned with compatibility of identity elements at any given point in time, continuity reflects consistency in identity over time (Amiot and Jaspal, 2014). Maintaining a sense of temporal continuity is important for identity. The assimilation of gay identity in the identity structure (i.e., accepting that one is gay) reflects a change in self-perception and self-definition. Similarly, its accommodation in the identity structure (i.e., the changes that are made in order for it to become part of the structure) can necessitate a change in self-perception in that one may need to rethink the importance of other identity elements. For instance, upon coming out as gay, a British Asian man may attempt to accentuate his masculinity to counteract dominant representations concerning gender and sexuality. The introduction of this novel information in the identity structure (i.e., masculinity) can, however, jeopardize the psychological thread that connects past, present, and future.

Indeed, participants in previous research have explicated threats to continuity. In one case, a young British Indian participant described how his family and friends began to treat him in a more feminine manner when he came out as gay. He reported feeling the need to demonstrate his masculinity by engaging in 'masculine activities' such as boxing and playing football. These changes in self-definition and behavior were viewed as necessary for enhancing self-esteem and distinctiveness (from 'typical' gay people), but were threatening for continuity. He had never viewed himself in this way before but felt compelled to do so.

In addition to affecting identity processes, nonheterosexuality can impact the formation and management of relationships.

Forming and Managing Relationships

Individuals manage their family and friendship networks in ways that benefit identity.

Family Relations

One significant barrier to coming out is fear of rejection from family members. For many British Pakistanis, non-heterosexuality is threatening at a psychological level, since there is a perception that is 'wrong' and 'sinful,' and at a social level, given that individuals may anticipate a negative response from others. Although British Indians may cease to experience threats at a psychological level later in the life span, many decide not to come out due to the fear of disownment (Jaspal, 2012b).

Some British Pakistanis may regard negative responses from family and ethnoreligious in-group members as legitimate due to the perceived 'sinfulness' of homosexuality. There may be an aspiration to 'turn' straight and sometimes even an endorsement of homophobia. Individuals may not have had any exposure to positive representations that construct homosexuality as an acceptable alternative to heterosexuality and, thus, there is a reliance on heteronormative social representations. Clearly, this is dependent partly on the interpersonal networks to which an individual has access, since group memberships are sources of social representations. Conversely, some British Indians, and particularly those who have had exposure to more positive representations of homosexuality, manifest a more defensive response to perceived homophobia from others. For instance, individuals may find it unacceptable that their family members are unable to see 'beyond' their sexual orientation, leading to negative interpersonal relations with their family and ethnocultural in-group members.

Marriage has emerged as a particularly salient issue in research with nonheterosexual British Asians (Jaspal, 2012b). Many British Asian families continue to observe the norm of arranged marriage. Heterosexual marriage is a religiocultural rite that Asian families eagerly await and, despite the growing acceptance of gay marriage in the West, among South Asians this is not generally viewed as a legitimate alternative. In early adulthood, nonheterosexual men may completely avoid the topic of (heterosexual) marriage by attenuating thoughts about it and by evading it as a topic of conversation Jaspal (2013). They may defer marriage by attaching priority to education, career development, financial stability, and the purchase of property – these are 'legitimate' activities that can delay marriage. However, individuals may ultimately reach a point at which it becomes increasingly difficult to deflect the topic of marriage and they must take a stance on it.

In some cases, this can present a psychological dilemma – in the short term, one might acquiesce in their family members' expectation that they be married but, in the long term, one's nonheterosexual orientation could mean that the marriage is not successful. This can potentially lead to a breakdown in family relations. Conversely, one might reject the established norm of (arranged) marriage, which could similarly cause a breakdown in family relations. Indeed, individuals have reported the perceived necessity of 'distancing' themselves from their families in order to avoid marriage without having to disclose their sexual orientation. The idea is that one sacrifices family relations in order to avoid both marriage and the necessity of coming out. A breakdown in valued interpersonal relations can be threatening for belonging and continuity, in particular.

Friendship Networks

The development of friendship networks among non-heterosexual British Asians often depends upon their level of involvement in gay affirmative social contexts or 'gay space' (e.g., nightclubs, bars, social groups). These contexts can provide social capital and, thus, "an environment for the establishment of resources, networks, relationships, norms, meanings and trust that enable smooth engagement among members" (Yip, 2007: p. 86). Gay space is used to varying degrees. Jaspal and Cinnirella (2012) have argued that nonheterosexual British Pakistani men may avoid frequenting gay space in order to avoid having to acknowledge their sexuality and avoid being outed. Conversely, nonheterosexual British Indians seem to be more willing to frequent gay space and indeed some of the lesbian, gay, bisexual, and transgender-themed Asian nightclub events have drawn large numbers of nonheterosexual Indian men and women, in particular (Bassi, 2008).

Participation in gay space can potentially have favorable outcomes for the development of interpersonal relations and ultimately for identity processes. This can allow temporary or long-term sociopsychological 'shielding' from the negative and stigmatizing social representations of homosexuality. Through the dissemination and exchange of positive representations in these spaces, individuals may come to perceive their sexual orientation as a facilitator of a positive group membership, rather than as a personal trait (cf Jaspal and Cinnirella, 2010).

Yet, gay space can expose nonheterosexual British Asian men to stigma on the basis of their ethnic and/or religious background. In their study on gay Muslims in the United States, Minwalla et al. (2005: p. 122) highlight the potential importance of 'race' within 'social dynamics within white gay culture.' Emerging empirical research suggests that nonheterosexual British Asian men may be excluded from gay space, either implicitly or explicitly, due to racism, or forced to become 'culturally white,' that is, to abandon elements of their ethno-religious identities in order to 'fit in' (Bassi, 2008). This may decrease willingness to partake in gay space to develop interpersonal relations with other nonheterosexual individuals.

Despite these potential obstacles, many men do indeed participate in gay space. There has been some research into the interpersonal dynamics in these settings (Jaspal and Cinnirella, 2012). Although intergroup relations between Indians and Pakistanis can be negative in many social contexts, gay space is one context in which points of tension and conflict with non-heterosexual British Asians can become latent. There is evidence of a superordinate ethnosexual group identity around being a 'gay Asian,' which cohesively brings together non-heterosexual British Pakistanis and Indians. Key to this 'gay identity' is a common understanding of the social and familial constraints (e.g., honor and arranged marriage) faced by non-heterosexual British Asians.

Conversely, individuals may avoid interpersonal relations with white British gay men since there are perceptions that they (1) are 'excessively' open about their sexual orientation and expect nonheterosexual people to be open about their orientation, (2) attach priority to relationships, want to 'settle down,' and therefore categorize themselves as gay, and (3) fail to understand the social and familial constraints faced by nonheterosexual British Asians. Recent research indicates that

interpersonal encounters with white British gay men can result in threats to self-efficacy, since individuals feel that they have less control over their relationships and lives (e.g., possibility of being outed by a culturally unaware white person).

On the other hand, for some British Asians, contact with white British gay men can in fact serve as an 'identity enhancer' (Jaspal and Cinnirella, 2012). Sustained interpersonal relations with white British gay men can provide individuals with the necessary social capital to reject negative representations of homosexuality, which are associated with their heteronormative ethnoreligious cultures. The cultural necessity of heterosexual marriage in early adulthood is one such example.

Positive social representations from their new alternative interpersonal networks can provide a more psychologically satisfying 'replacement' of negative representations regarding their sexual orientation. Moreover, these networks can allow individuals to perceive their sexual orientation as 'normal' and, conversely, the negative reactions of their cultures and families as 'abnormal.' In short, self-alignment with white British gay men can have socially and psychologically empowering outcomes, resulting in the assimilation–accommodation and positive evaluation of their sexual orientation.

Conclusion

Nonheterosexual British Asian men can face social and psychological challenges to identity and well-being as a result of their sexual orientation. This article explores meaning-making vis-à-vis sexuality at the individual level, dominant social representations of homosexuality, how these representations might impinge upon identity, and how individuals, accordingly, manage social relations. This study focuses exclusively upon nonheterosexual men, and it is difficult to generalize these research findings to nonheterosexual British Asian women given the dearth of relevant research. It is, however, noteworthy that in most South Asian ethnoreligious communities, nonheterosexuality is viewed as contravening masculinity norms, in particular, and the act of 'sodomy' (anal intercourse between men) is viewed as particularly morally revulsive. Thus, there may be less acknowledgment of lesbianism and bisexualism among women and more scope for nonheterosexual British Asian women to remain socially 'hidden.' There is clearly a need for research into the identities and experiences of nonheterosexual British Asian women.

Existing research suggests that negative representations of homosexuality seem to be prevalent in family and ethnocultural/ethnoreligious contexts. In the long term, it is necessary to attempt to create a shift in social representations so that these communities adopt a more accepting stance on homosexuality. Drawing on social representations theory, this will necessitate positive forms of anchoring and objectification in relation to homosexuality. This may in turn encourage individuals to assimilate–accommodate and positively evaluate their nonheterosexuality. In the short term, it would be beneficial for nonheterosexual British Asians to gain some exposure to positive social representations of homosexuality, which might in turn facilitate the construction of a positive sexual identity. The task of facilitating positive identification among this population will need to be undertaken by a variety of actors – researchers, policy makers, educators, and community leaders alike.

Nonparametric Regression

Martin L Hazelton, Institute of Fundamental Sciences, Massey University, Palmerston North, New Zealand

Abstract

Nonparametric regression is a methodology for describing the trend between a response variable and one or more predictors. This approach differs from classical regression models in that it does not rely on strong assumptions regarding the shape of the relationship between the variables. Rather, the data are allowed to speak for themselves in determining the form of the fitted regression functions. Approaches include kernel smoothing and local polynomial regression, spline-based regression models, and regression trees and related techniques. Additive models are typically employed when there are several predictors to mitigate problems arising from the curse of dimensionality.

Introduction

Suppose that one is confronted with a data set comprising observations on multiple variables. An initial exploration of this data set would typically include visualization and computation of numerical summaries for individual variables. However, often it is the relationships between the variables that are of greater interest. Scatterplots of pairs of variables can provide some insight: it is often helpful to produce a matrix of all such possible plots, sometimes referred to as a 'pairs plot.'

As an illustration, we consider data from a UNICEF report from 2003 (UNICEF, 2003), describing childhood mortality and associated indicators by country. The variables recorded (where available) are listed in Table 1. A pairs plot of the data appears in Figure 1. There are some obvious pairwise relationships between variables. In some cases these appear approximately linear; for example, between **Under.5.MR** and **Infant.MR**. In other cases the forms of the relationships are more complicated. Consider the plots of **Infant.MR** against **GNI.per.cap**, or **Under.5.MR** against **Hi.20.pc** for instance.

Interpretation of scatterplots can be aided by adding smooth curves that describe the trend between the variables. Consider for example the plots in Figure 2. The left-hand panel contains data on **Infant.MR** against **GNI.per.cap**, while the right-hand panel shows the logarithm of **Under.5.MR** against **Hi.20.pc**. In both cases 'scatterplot smoothers' have been employed to help draw out the form of the relationships between the variables. In the left-hand panel the rapid rise in under-5 mortality as the share of income enjoyed by the richest 20% increases from 35 to 45% is quite striking, and is a feature of the data that arguably could have been missed without the scatterplot smoothing.

Table 1 Variables for the 2003 UNICEF data set

Variable	*Description*
Under.5.MR	Mortality rate for children under 5 years of age (per 100 000)
Infant.MR	Mortality rate for children under 1 year of age (per 100 000)
Total.pop	Total population (1000s)
Births	Annual number of births (1000s)
GNI.per.cap	Gross national income per capita (USD)
Life.exp	Life expectancy at birth (years)
Adult.lit	Adult literacy rate (%)
School	Attendance rate at primary school (%)
Low.40.pc	Percentage share of household income held by the poorest 40%
Hi.20.pc	Percentage share of household income held by the richest 20%

The trend curves displayed in Figure 2 were obtained using a type of nonparametric regression. Regression models in general seek to describe the variation in the mean (of expected value) of one variable, the response, as a function of one or more predictor (or explanatory) variables. In traditional parametric regression models, this relationship is assumed to be linear (or possibly to be quadratic or some other low order polynomial). However, in nonparametric regression we make almost no assumptions about the shape of the relationship, letting the data 'speak for themselves' in determining the estimated trend. While the plots in Figure 2 demonstrate the application of kernel regression to bivariate data (i.e., response and a single predictor variable), this type of methodology can also be employed with higher dimensional data, as discussed later.

An important use of nonparametric regression is as a tool for data exploration and visualization, where the aim is to gain a preliminary feel for the data before conducting any formal model fitting. Nonparametric regression can be employed for a number of other tasks, including prediction and hypothesis testing (e.g., Azzalini and Bowman, 1993). Nonparametric regression can also be combined with parametric models to form hybrid semiparametric models; see for example Ruppert et al. (2003).

Nonparametric Regression with a Single Predictor

We first look at the situation where we have bivariate observations (x_i, y_i) for $i = 1, \ldots, n$. A very general kind of regression model describing the relationship between these variables can be written as

$$y_i = m(x_i) + \varepsilon_i \quad (i = 1, \ldots, n) \qquad [1]$$

where $\varepsilon_1, \ldots, \varepsilon_n$ are error terms that are assumed to have zero mean, so that $m(x_i) = \mathrm{E}[y_i|x_i]$. The regression function, m, therefore describes how the conditional mean of y depends on x.

Figure 1 Pairs plot of the UNICEF data.

We can obtain the classical linear regression model from eqn [1] by setting $m(x) = \beta_0 + \beta_1 x$. In that case m is described in terms of just two parameters (the coefficients β_0, β_1) and so the regression model is parametric. In nonparametric regression, we do not specify any particular (simple) parametric form for m, we merely assume that it is some (typically smooth) function of x.

Nonparametric regression is characterized by 'local estimation' of the regression function. To understand what this means, consider estimation of m at a particular value x of the predictor variable. In linear regression we would form the estimate $\widehat{m}(x) = \widehat{\beta}_0 + \widehat{\beta}_1 x$ where $\widehat{\beta}_0$ and $\widehat{\beta}_1$ are parameter estimates (usually obtained by the method of least squares in this context). Now, these parameter estimates are functions of all the observations. It follows that each observed data point (x_i, y_i) has an impact on the estimate $\widehat{m}(x)$, no matter how close or distant x_i is to the estimation point x. Classical linear regression is therefore based on 'global estimation.' In contrast, when estimating $m(x)$ locally, information is used only from data points with predictor values relatively close to x.

Kernel Smoothing

Perhaps the most straightforward method of nonparametric regression is to estimate $m(x)=\mathrm{E}[y|x]$ using a local average. Specifically, we can estimate the regression function at any

Figure 2 Plot of infant mortality against per capita GNI (left panel (a)) and under-5 mortality against share of household income held by the richest 20% (right panel (b)). In both cases nonparametric regressions have been added to help draw out the form of the relationships between the variables.

given point x by computing the (local) average of all data within some window centered on x. By sliding this window along the x-axis we will generate an estimate of the entire regression function (i.e., obtain estimates of $m(x)$ for all estimation points). We illustrate this idea for a regression of log (**Under.5.MR**) against **Hi.20.pc** in Figure 3, where the shaded regions in the left-hand panel represent instances of the estimation window. The resultant regression curve (shown right-hand panel) tracks the data quite well, but has an unattractively uneven appearance. Its blocklike form arises from sudden changes in the local mean that occur when a data point enters or leaves the window.

This problem can be addressed by replacing the local average by a weighted local average, where the weight for response y_i decreases smoothly according to how distant the predictor x_i is from the estimation point x. A convenient way of

Figure 3 Illustration of local averaging to produce a regression of the logarithm of under-5 mortality against share of household income held by the richest 20%. In the left-hand panel (a) we show how estimates at $x = 37$ and $x = 57$ (located at the vertical dotted lines) are formed. In each case the estimated regression function, indicated by a cross, is obtained by computing the mean y-value for all data points falling in the surrounding shaded area. By computing such local averages for all values of x we obtained the estimated regression function depicted in the right-hand panel (b).

defining the weights is through a 'kernel function.' A kernel function K typically takes nonnegative values, and is unimodular and symmetric about zero. Examples include the Epanechnikov kernel defined by $K(x) = \frac{3}{4}(1-x^2)1_{|x|<1}$; the biweight kernel given by $K(x) = \frac{15}{16}(1-x^2)^2 1_{|x|<1}$; and the Gaussian kernel given by $K(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$. These are plotted in Figure 4. In each case we can define the relative weight allocated to observation i for estimation at point x by $K(x-x_i)$.

Before we proceed, however, we need to address the question of scale. Specifically, how wide should we make the estimation window? In Figure 3, for example, we used a window of total width 7 for the local averaging. However, applying a window of the same width to the data on **Infant.MR** against **GNI.per.cap** from the left-hand panel of Figure 2 would clearly be inappropriate. For many x values, windows of that width would contain no data. A similar objection applies to using the kernels in Figure 4 without modification. To address this issue, we introduce a scaling parameter h called the 'bandwidth.' A scaled version of the basic kernel can then be defined by $K_h(x) = h^{-1}K(x/h)$.

Using the scaled kernel to defining weights, we can define a nonparametric regression estimator using local weighted averaging as follows:

$$\widehat{m}_{\mathrm{NW}}(x) = \frac{\sum_{i=1}^{n} y_i K_h(x-x_i)}{\sum_{j=1}^{n} K_h(x-x_j)} \qquad [2]$$

The denominator in eqn [2] means that the weight for the ith observation is $w_i = K_h(x-x_i)/\sum_{j=1}^{n} K_h(x-x_j)$, ensuring that $\widehat{m}_{\mathrm{NW}}(x)$ is a bona fide weighted average because $\sum_{i=1}^{n} w_i = 1$. The nonparametric regression defined by eqn [2] is often referred to as the Nadaraya–Watson estimator after its contemporaneous developers (Nadaraya, 1964; Watson, 1964), explaining the NW subscript to $\widehat{m}$. Its construction and application is illustrated in Figure 5.

The chosen value for the bandwidth h is of critical importance to the appearance of the fitted local regression. A very small bandwidth leads to weighted local averaging that involves only a very small number of data points. This results in an estimate with high variance, but low bias. The regression curve will appear undersmoothed, with multiple wiggles as it tracks noise as well as signal. A large bandwidth involves estimation over many more data points, reducing variability but introducing high bias because data points very distant to the estimation point play a significant role. The resultant regression curve will be oversmoothed, quite possibly failing to pick up interesting structure in the data. We illustrate these ideas in Figure 6.

A variety of practical methods of bandwidth selection have been proposed. The simplest is to choose h by eye, in order produce an aesthetically pleasing plot. Less subjective approaches include cross-validation and plug-in methods. The former seeks to choose the bandwidth that is best for predicting the response for observations independent from those used to estimate the regression. The latter uses asymptotic theory to derive a mathematical expression for the optimal bandwidth; that is, the bandwidth minimizing the mean squared error of $\widehat{m}_{\mathrm{NW}}$ integrated over the range of the predictor variable. Unknown quantities in the formula are replaced by pilot estimates thereof, producing a data-driven bandwidth. See Wand and Jones (1995) for details.

Local Polynomial Regression

The Nadaraya–Watson estimator can be derived as the solution to an optimization problem. Specifically, $\widehat{m}_{\mathrm{NW}}(x) = \widehat{\beta}_0$ where $\widehat{\beta}_0$ is the minimizer of the weighted sum of squares,

$$Q_0(\beta_0) = \sum_{i=1}^{n} K_h(x-x_i)(y_i-\beta_0)^2 \qquad [3]$$

A useful interpretation of this mathematics is that the Nadaraya–Watson estimate results when we fit a locally constant regression function $m(x) = \beta_0$ to the data by the method of least weighted sum of squares.

This idea can then be generalized. Suppose that we use a linear approximation of the regression function, so that at a point z close to the estimation point x we have $m(z) \approx \beta_0 + \beta_1(z-x)$. We can obtain parameter estimates $\widehat{\beta}_0$ and $\widehat{\beta}_1$ as the minimizer of the weighted sum of squares,

$$Q_1(\beta_0,\beta_1) = \sum_{i=1}^{n} K_h(x-x_i)[y_i-\beta_0-\beta_1(x_i-x)]^2 \qquad [4]$$

These estimates provide the closest possible match of the approximate linear function to the true regression function. Moreover, since $m(x) \approx \beta_0 + \beta_1(x-x) = \beta_0$, it follows that

Figure 4 Three popular types of kernel function.

Figure 5 Nadaraya–Watson kernel regression for the logarithm of under-5 mortality against share of household income held by the richest 20%. The left-hand panel (a) shows how the estimate of the regression function is obtained at $x = 57$, with the weights derived from the Gaussian kernel function depicted at the top of the plot. The gray-scale intensity of each data point in the left-hand scatterplot reflects its weight for estimation at that point. The estimate of the regression function at $x = 57$ is marked by a cross. The right-hand panel (b) displays the complete nonparametric regression curve. A bandwidth of $h = 3$ was employed.

the value of the estimate $\widehat{\beta}_0$ the regression function at x. It is called the local linear estimator, which we will denote by $\widehat{m}_{\mathrm{LL}}(x)$. Its construction is illustrated in Figure 7. One of the advantages of local linear regression over the Nadaraya–Watson estimator is better performance near boundaries. This is illustrated in the middle- and right-hand panels of Figure 7, where the former methodology avoids the unnatural flattening near $x = 0$ that is observed in the curve using the latter approach.

We can generalize further, and seek to approximate $m(x)$ locally by a polynomial of degree p. If this is fitted by minimizing the kernel weighted sum of squares once again, then

Figure 6 The effect of bandwidth on Nadaraya–Watson kernel regression. In the left-hand panel (a) a very small value $h = 0.5$ is used for the bandwidth, resulting in undersmoothing. In the right-hand panel (b) the fitted nonparametric regression is oversmoothed through the use of the large bandwidth $h = 10$.

Figure 7 Local linear regression for the infant mortality against share of GNI per capita (USD). The left-hand panel (a) illustrates construction of the estimate at $x = 8000$. The gray-scale intensity of the points indicates the weights attached to each point when fitting the regression line. The cross indicates the local linear estimate at the point $x = 8000$. The middle panel (b) shows the complete local linear regression curve, while the right-hand panel (c) displays the Nadaraya–Watson estimate for comparison. Note how the local linear estimator provides a more plausible fit to the data near the boundary at $x = 0$. All estimates were computed using a bandwidth of $h = 8000$ and a Gaussian kernel.

we get the order p local polynomial estimator $\widehat{m}_p(x)$ by following the same kind of steps as above. The Nadaraya–Watson estimator is simply the order $p = 0$ local polynomial estimator, and hence is sometimes referred to as the local constant estimator.

For practical implementation of local polynomial regression we have a number of choices to make, concerning the order p of polynomial, the kernel function, and the value of the bandwidth. With regard to the first of these choices, local linear regression (corresponding to $p = 1$) is a popular and effective, in part, because of its good behavior near boundaries. Both theory and practice have shown that the choice of kernel function is of relatively minor importance; the biweight and Gaussian kernels are commonly used. The selection of the bandwidth h is far more critical. Major approaches to bandwidth selection for local polynomial regression mirror those discussed earlier in the context of the Nadaraya–Watson estimator. See Fan and Gijbels (1996) for further discussion of these matters.

LOWESS (an acronym of locally weighted scatterplot smoothing) and its close cousin LOESS are popular variants of local polynomial kernel regression (Cleveland, 1981). The principal difference between LOWESS (and LOESS) and the methods described above is that the local polynomial is fitted by weighed least squares to all data within a window the width of which is adjusted to contain a fixed proportion of the data. This is effectively local polynomial regression in which the bandwidth h for estimation at the point x adapts to the density of data close to x. The proportion of data determining the estimation window is called the 'span.' The fitted curves in Figure 2 were obtained using LOESS.

Regression with Splines

Spline smoothing provides an alternative approach to nonparametric regression. A spline is constructed by dividing the x-axis into a sequence of intervals. The spline is defined by different polynomials on each interval, but in such a way that these functions tie together smoothly at the 'knots,' i.e., the interval boundaries. The spline is said to be of pth order if its constituent polynomials are of that degree. A pth order spline must be $p - 1$ times differentiable at the knots.

Splines provide a very flexible class of functions for regression. Spline-based regression models have a nonparametric nature because the division of the x-axis into intervals means that estimation is essentially local. Nonetheless, splines are defined in terms of a large number of parameters – a number that is unbounded if the number of knots is allowed to increase indefinitely with the sample size n. This apparent paradox simply reflects the slightly misleading nature of the nomenclature 'nonparametric regression,' which nowadays is interpreted as a regression methodology that is local in nature.

The simplest variety is the linear (i.e., $p = 1$ order) spline, which is sometimes referred to as the broken stick model. A linear spline can be expressed as

$$s(x) = \beta_0 + \beta_1 x + \sum_{j=1}^{J} b_j (x - \kappa_j)_+ \qquad [5]$$

where $\kappa_1, \ldots, \kappa_J$ are the locations of J knots for the spline, and $(a)_+ = \max(0, a)$ for any number a. For a point $x < \kappa_1$, we have $s(x) = \beta_0 + \beta_1 x$. At the first knot the slope jumps by b_1, and hence the coefficient of x becomes $(\beta_1 + b_1)$ for $\kappa_1 \le x < \kappa_2$. The slope adjusts at each subsequent knot by the amounts specified by the parameters $b_2, \ldots, b_J$. This is illustrated in the left-hand panel of Figure 8.

A general pth order spline is given by

$$s(x) = \beta_0 + \beta_1 x + \cdots + \beta_p x^p + \sum_{j=1}^{J} b_j (x - \kappa_j)_+^p \qquad [6]$$

where the change at knot j is to the coefficient of $(x - \kappa_j)^p$. As an example, consider the following quadratic ($p = 2$) spline with a single knot at $\kappa_1 = 1$:

$$s(x) = 5 + 4x + 3x^2 + 2(x - 1)_+^2$$

Figure 8 Some linear splines. The left-hand panel (a) illustrates the construction of a linear spline with knots at $x = 3$, 6, 9, marked by dotted vertical lines. To the left of the first knot the equation of the spline is $s(x) = 2 + x$. The slope then changes by $b_1 = -1.5$ at $\kappa_1 = 3$, and hence the coefficient of x is -0.5 for $3 \le x < 6$. The slope changes by $b_2 = 0.5$ and $b_3 = 0.9$ at the two subsequent knots. The central (b) and right-hand (c) panels depict linear splines fitted to the data on logarithm of under-5 mortality against share of household income held by the richest 20%. Locations of knots are indicated by the tick marks on the x-axis. The spline in the central panel is fitted using the method of least squares, and that in the right-hand panel is fitted using penalized least squares.

The quadratic equation defining the spline is different either side of the knot. We have

$$s(x) = 5 + 4x + 3x^2$$

when $x \le 1$, and

$$\begin{aligned} s(x) &= 5 + 4x + 3x^2 + 2(x-1)^2 \\ &= 7 + 5x^2 \end{aligned}$$

when $x \ge 1$.

We can use splines for nonparametric regression by replacing the general regression function m in eqn [1] by a spline s, so that $y_i = s(x_i) + \varepsilon_i$ (for $i = 1, \ldots, n$). Despite their flexibility, spline-based nonparametric regression is a linear model because the response y is a linear combination of the model parameters $(\beta_0, \ldots, \beta_p, b_1, \ldots, b_J)$. This means that splines can in principle be fitted to the data using the method of least squares. However, splines are so heavily parameterized that we will get severe over-fitting if this approach is employed without modification. This is illustrated in the middle panel of **Figure 8**, where a linear spline is fitted to the data on **Under.5.MR** against **Hi.20.pc**. The resultant regression curve is very jagged and noisy. This occurs because the changes to the slope of the spline, described by the parameter estimates $\widehat{b}_1, \ldots, \widehat{b}_J$, are too extreme. This is not a problem peculiar to linear splines. We would also get a noisy curve were we have to fit a higher order spline $(p \ge 2)$ using the method of least squares.

We can hope to get a more aesthetically pleasing, smooth fit if we reduce the magnitude of parameter changes at the knots. This motivates estimation of parameters based on minimization of a penalized sum of squares,

$$Q(\boldsymbol{\beta}, \mathbf{b}) = \sum_{i=1}^{n} \{y_i - s(x_i)\}^2 + \alpha \sum_{j=1}^{J} b_j^2 \qquad [7]$$

where α is a tuning parameter. In eqn [7] the standard sum of squares criterion (the first term of the right) is augmented by a penalty (the second term on the right) that is increasingly severe as the parameters $b_1, \ldots, b_J$ increase in magnitude. As a consequence, the estimates for this group of parameters obtained by minimizing eqn [7] will be shrunk toward zero in comparison to standard least squares estimates. This is illustrated in the right-hand panel of **Figure 8**, where a linear spline is fitted to the data on **Under.5.MR** against **Hi.20.pc** using the method of penalized least squares.

In order to implemented spline-based regression modeling in practice we need to make a number of choices, including selecting the degree of the spline and the number and position of the knots. With regard to the former, cubic splines $(p = 3)$ are most widely used because of their smoothness properties. Turning to the choice of knots, we could place a knot at each unique value of the predictor variable. This produces a class of models called 'smoothing splines' (Wegman and Wright, 1983; Green and Silverman, 1993). A very popular alternative is to select a much smaller number of knots, often following the rule of thumb $J = \min(35, \lfloor n/4 \rfloor)$ where $\lfloor a \rfloor$ denotes rounded down to the nearest integer. Models with this reduced number of knots, and which are fitted by minimization of eqn [7], are called 'penalized regression splines' (Eilers and Marx, 1996). The placement of the knots is not usually critical. Standard approaches are to space the knots evenly across the range of the predictor, or to place them at regular quantiles thereof (cf Ruppert, 2002).

A more significant issue is choice of the value of the tuning parameter α in eqn [7]. A relatively large value of α implies particularly heavy penalties for large estimates $\widehat{b}_1, \ldots, \widehat{b}_J$, and hence will tend to produce a smooth fitted spline with only minor changes to coefficients at the knots. Conversely a small value of α indicates only a weak effect for the penalty term, and hence a model fit little different to that obtained using standard least squares. A number of approaches to selecting α have been considered, including cross-validation, generalized cross-validation, and likelihood-based methods (cf Kauermann, 2005). The degree of smoothing in the linear spline in the right-hand panel of **Figure 8** was chosen using likelihood methods.

Nonparametric Regression with Multiple Predictor Variables

We have focused thus far on regression involving a single predictor. When there are multiple predictors, $x_1, \ldots, x_r$, the most general form of nonparametric regression model is

$$y_i = m(x_{i1}, \ldots, x_{ir}) + \varepsilon_i \quad (i = 1, \ldots, n) \qquad [8]$$

where x_{ij} is the value of the jth predictor for the ith observation. The regression function m now describes the variation in the conditional mean of y in terms of all the predictors, in an entirely general way.

Local polynomial kernel regression extends quite simply to this multiple predictor case. In the case of local constant regression, the estimate regression function still follows the form of eqn [2], but with the scalars x and x_i replaced respectively by vectors $\mathbf{x} = (x_1, \ldots, x_r)^T$ and $\mathbf{x}_i = (x_{i1}, \ldots, x_{ir})^T$. The multivariate (scaled) kernel function $K_h(\mathbf{x} - \mathbf{x}_i)$ continues to define the weights used in the local averaging process. A popular choice is the multivariate Gaussian kernel, the bivariate version of which is plotted in **Figure 9(a)**. There are a number of types of scaling that can be applied to multivariate kernels, including different values for the bandwidth for each predictor (a necessity unless the predictors are pretransformed to a common scale). For pth order local polynomial regression the methodology continues to involve optimization of weighted sums of squares akin to eqn [4], although the polynomials will now be in terms of the multiple predictor variables. We illustrate local constant kernel regression of **Under.5.MR** on **Adult.lit** and **Hi.20.pc** in **Figure 9(b)**.

Fitting the nonparametric regression from eqn [8] is useful and viable only when the dimension r of the predictor variables is modest. An immediate practical problem is visualization of the fitted models. This is possible when $r = 2$ (for example, using perspective plots as in **Figure 9**, contour plots or heat maps), but not in higher dimensions. Of course, nonparametric regression models with $r \geq 3$ can be used for other purposes than visualization (e.g., prediction). However, estimation of such models rapidly becomes more difficult as r increases because of the 'curse of dimensionality,' which in essence requires the sample size to increase exponentially with r in order to retain any given level of precision.

To explain more fully the curse of dimensionality, suppose that we are interested in estimation of the regression function at a point $\mathbf{x}_0 = (x_{01}, x_{02}, \ldots, x_{0r})^T$. To start with, consider the case with a single predictor (i.e., $r = 1$) and suppose that 1/10 of the data have an x-value that falls within a window of length $2h$ centered on the estimation point (where h is the bandwidth). We can expect to compute a serviceable local average from this fraction of the data even for samples as small as $n = 100$. If we had $r = 2$ independent predictors with the same marginal property, then only $(1/10)^2 = 1/100$ of the data will fall in a square estimation window centered on the estimation point and with sides of length equal to $2h$. For r predictors of this type, only a fraction $(1/10)^r$ of the data will be within an r-dimensional hypercube window centered on $\mathbf{x}_0$ and with side lengths $2h$. Even with a sample size as large as $n = 10\,000$, we would probably see no data within such a window around the estimation point when there are $r = 6$ predictors.

A common method of addressing this problem is to assume that the effects of the predictors can be expressed in additive form, so that

$$y_i = \beta_0 + m_1(x_{i1}) + \cdots + m_r(x_{ir}) + \varepsilon_i \quad (i = 1, \ldots, n) \qquad [9]$$

where the regression functions $m_1, \ldots, m_r$ are each specific to a single predictor, and hence not subject to the curse of dimensionality. The term β_0 in eqn [9] models the 'grand mean' for the response, while each of the individual functions $m_1, \ldots, m_r$ is centered at zero on the response scale. It should be recognized that replacing the general model in eqn [8] by the additive model [9] requires the (strong) assumptions that there are no interactions between predictors. In other words, the relationship between y and predictor x_j is assumed to be the same regardless of the values taken by the other predictors.

The additive model defined by eqn [8] is often fitted using splines to represent the functions $m_1, \ldots, m_r$. See for example Wood (2006). The fitting algorithms employ penalized least squares. An advantage of using splines is that their linear model structure makes inference relatively straightforward, so that it is reasonably easy to derive quantities like standard errors and confidence intervals. The estimated functions $\widehat{m}_1, \ldots, \widehat{m}_r$ can be visualized to provide an impression of the relationship between the response and any given predictor, having taken account of the effects of the other predictors. This is illustrated in **Figure 10**, where we display results for the additive model

$$\begin{aligned} \mathsf{E}[\log(\mathbf{Under.5.MR})] = {} & \beta_0 + s_1(\mathbf{Adult.lit}) + s_2(\mathbf{Hi.20.pc}) \\ & + s_3(\mathbf{School}) + s_4(\mathbf{Low.40.pc}) \end{aligned}$$

where $s_1, \ldots, s_4$ are cubic spline representations of the component regression functions $m_1, \ldots, m_4$, respectively.

Other Models and Methods of Nonparametric Regression

Regression Trees and Related Methods

A wide variety of methods of nonparametric regression have been proposed. Many can be regarded as variations and extension of the kernel local polynomial regression and spline techniques discussed above.

One important class of models with somewhat different foundations comprises recursive partitioning methods (Breiman et al., 1984). These seek to divide the data into small groups of similar observations, and then estimate the mean response within the group by the group mean. In binary regression tree models, the partitions develop through a sequence of binary splits. In more detail, each partition involves splitting one of the current groups according to a division at some value of one of the predictor variables. The choice of variable and split value is made so as to minimize the residual sum of squares. This methodology is illustrated in **Figure 11**. Regression trees of this sort can be effective tools for prediction, but are less well suited to data visualization because they produce piecewise constant regression curves, as per the right-hand panel of **Figure 11**.

Multivariate adaptive regression splines (MARS) can be regarded as a generalization of regression trees that are better suited to handling continuous numerical predictors (Friedman,

Figure 9 (a) a perspective plot of a bivariate Gaussian kernel. (b) a perspective plot of a local constant kernel regression of logarithm of under-5 mortality against adult literacy rate and share of household income held by the richest 20%, superimposed on a three-dimensional scatterplot of the data.

1991). While regression trees can be thought of as zero-order splines (since they are piecewise constant functions), MARS is based on linear splines. MARS is an adaptive method in the sense that the locations of the knots are not prespecified, but rather are selected in order to optimize fit to the data. The name 'MARS' is trademarked to Salford Systems, and as a consequence open-source implementations of this general methodology are often called 'Earth.'

Figure 10 Estimates of component regression functions for an additive model relating logarithm of under-5 mortality to (a) adult literacy rate (%), (b) attendance rate at primary school (%), (c) share of household income held by the poorest 40%, and (d) share of household income held by the richest 20%. Each regression function is centered on zero on the response scale, and hence represents a change from the overall mean response. The shaded areas indicate 95% confidence intervals for the fitted curves.

Nonparametric Regression for Binary and Count Data

The methods discussed above are intended for use with a continuous numerical response variable y, typically assumed to follow a normal distribution conditional on x. However, nonparametric regression can also be employed to describe trends when the response y is binary (e.g., yes/no, died/survived) or a count (particularly a count sufficiently small that a continuous approximation is unappealing). A common and effective generalization of the additive model in eqn [9] is to model a transformed version of the mean response, so that

$$g(\mu_i) = \beta_0 + m_1(x_{i1}) + \cdots + m_r(x_{ir}) \qquad [10]$$

where $\mu_i = \mathrm{E}[y_i]$. The choice of 'link' function g depends on the nature of the response variable. For a binary response coded 0 or 1, the mean response is $\mu_i = \mathbb{P}(y_i = 1)$ and a natural choice of link is the logit transform $g(\mu) = \log(\mu/(1-\mu))$. For a Poisson distributed count response, $g(\mu) = \log(\mu)$ is natural. Equation [10] defines a class of models called generalized additive models, which can be regarded as nonparametric versions of classical generalized linear models. See Hastie and Tibshirani (1990).

Software Implementation

Most modern statistical software packages include an implementation of at least some basic types of nonparametric regression model, but the availability of more sophisticated techniques is patchy. Probably the most routinely available method is LOESS, which is implemented in Minitab, SPSS, Stata, SAS and R, amongst many others. Regression trees are also implemented in a wide variety of packages. Kernel local polynomial regression, penalized spline regression, and generalized additive models are less common. Nonetheless,

Figure 11 Regression tree for data on logarithm of under-5 mortality against share of household income held by the richest 20%. The left-hand panel (a) displays the tree defining the recursive partition of the data. Observations satisfying the inequalities at nodes proceed down left-hand branches; those failing to do so go down right-hand branches. Fitted values are given at terminal nodes (leaves) at the bottom of the plot. The right-hand panel (b) displays the resultant regression curve.

both SAS and R have algorithms for all of these techniques, and in the latter case a number of versions thereof.

Abstract

Statistical methods are useful in obtaining information about the unknown state of nature or the 'parameter' as it is usually referred to in the literature. A statistician collects suitable data whose distribution depends on the unknown parameter. A statistical inference procedure is then devised to produce information about the unknown parameter or a function of that parameter. The classical methods of inference assume that the probability distributions that govern the data depend only on a few unknown quantities (or parameters). Such procedures are called parametric procedures. When one is not able to make such strong assumptions about the probability models that govern the data, and/or when one can be more certain of the rankings among the data than the exact values, one uses robust inference procedures known as nonparametric methods. Tests and estimates based on the simpler nonparametric methods can be obtained from easy computations based on the data. Procedures that have validity under more general models will require more heavy computations. When there is some uncertainty about the probability models and/or when expert information concerning the problem at hand is available, one should use Bayesian methods. These methods can also tend to be computationally intensive. We describe briefly the main ingredients of some new Bayesian and computational methods in nonparametric inference. These include bootstrapping and Gibbs sampling.

Standard inference procedures are based solely on data whose probability distributions have been specified in terms of a few parameters. Bayesian methods incorporate existing knowledge (historical information, expert knowledge, previous data, etc.) about the parameter into the inference process. This is done by assigning a probability distribution, called the prior distribution, to the parameter governing the distribution of the data. This prior distribution represents the information available to us concerning the parameter before gathering data. After some data have been observed, we can compute the conditional distribution of the parameter given the observed data; this is called the posterior distribution and it represents our knowledge of the parameter at this stage. If one wants to estimate a function of the parameter, then one can just find the expectation of that function under this posterior distribution; it will be the best estimate under squared error loss. Similar methods of estimation under other loss functions are possible and they all depend solely on the posterior distribution. Thus Bayesian methods concentrate first on finding the posterior distribution or on simulating from the posterior distribution.

In a nonparametric problem, the common unknown distribution F of the data is the 'parameter.' A Dirichlet measure is a distribution for F and will serve as a prior distribution in nonparametric problems. The real problems here are how to define such nonparametric prior distributions for this and other wider classes of problems, and how to carry out the necessary computations.

In Section Bayesian Methods and Dirichlet Measures below we describe various ways to define the Dirichlet measure, which is a natural choice for a prior distribution in nonparametric problems. Closed form solutions for inference in Bayesian nonparametric problems are given in several cases together with some references for further study.

Since closed form solutions will in general not be available in interesting situations, advanced computational approaches are necessary to carry out inference in nonparametric Bayesian problems. Such computational methods have been used in regular nonparametric problems as well. In Sections Testing for Concordance and Testing Independence we give examples of computational intensive methods in two standard nonparametric problems, namely testing for independence and testing for concordance of two variables. In Section Gibbs Sampling, the estimation of a distribution function when observations have been censored by some censoring mechanism is treated as a Bayesian nonparametric problem. We describe the advanced computational approach, known as Gibbs sampling, which can be used for this problem. We present the exact Bayes estimate and the Bayes estimate obtained by Gibbs sampling to demonstrate that power of the computational method. For further comparison purposes, the estimate previously obtained by frequentist methods is also presented.

Bayesian Methods and Dirichlet Measures

Bayesian methods are quite general and apply to both parametric and nonparametric inference problems. It is easier in the parametric case since the unknown parameter usually varies in a finite dimensional space and we are familiar with probability distributions in finite dimensional spaces. In nonparametric problems the unknown 'parameter' can be as complex as the underlying distribution of the observed random variable. This is not only an infinite dimensional quantity, it also satisfies some inequality restrictions; for instance a distribution function $F(x)$ satisfies $0 \leq F(x) \leq 1$ for all $x \in R_1$, where R_1, is the real line, and is also a nondecreasing right continuous function with limits 0 and 1 as x tends to $-\infty$ and ∞, respectively. Thus the first problem faced by Bayesians in nonparametric inference problems is an appropriate definition of a probability distribution for $F(\cdot)$. Any such prior distribution will be useful only if it is tractable and yields closed form or computable solutions to the nonparametric inference problems on hand. These problems were daunting at first, but were elegantly solved by Ferguson (1973) who introduced Dirichlet measures as prior distributions.

We will look closely at probability measures P (which are equivalent to distribution functions) on R_1, the real line. The same can be done for probability measures on more general spaces. For any partition of $\mathscr{A} = (A_1, \ldots, A_k)$consisting of disjoint measurable sets whose union is R_1, the vector $P(\mathscr{A}) = [P(A_1), \ldots, P(A_k)]$ is a k-vector of nonnegative numbers adding to 1. Notice that P is completely determined if $P(\mathscr{A})$ is known for all or most partitions $\mathscr{A}$ and satisfies obvious additivity and consistency conditions. It can be shown that a consistent family of probability measures for $P(\mathscr{A})$ as $\mathscr{A}$ varies among all finite partitions will define a unique probability measure for P. This is the approach of Ferguson (1973).

To describe Ferguson's Dirichlet measure, we will first look at finite dimensional Dirichlet distributions. These are distributions in R_k concentrated on the subset

$$\mathscr{P}_k = \left\{\mathbf{p} = (p_1, \ldots, p_k); \quad p_1 \geq 0, \ldots, p_k \geq 0, \quad \sum_i p_i = 1\right\}$$

A random vector $(Y_1, \ldots, Y_k) \in \mathscr{P}_k$ is said to have a finite dimensional Dirichlet measure with parameters $(\beta_1, \ldots, \beta_k)$ with $\sum_j \beta_j > 0$, if $Y_i = Z_i/(\sum_j Z_j)$ where $Z_1, \ldots, Z_k$ are independent Gamma random variables with scale parameter 1 and shape parameters $\beta_1, \ldots, \beta_k$ respectively. When $\beta_i > 0$, $i = 1, \ldots, k$, this distribution is given by the more familiar density function of$(Y_1, \ldots, Y_{k-1})$:

$$\frac{\Gamma\left(\sum_i \beta_j\right)}{\Pi_j \Gamma(\beta_j)} \prod_j y_j^{\beta_j - 1}$$

where $y_k = 1 - \sum_1^{k-1} y_j$. This finite dimensional Dirichlet measure will be denoted in symbols by $\mathscr{D}(\beta_1, \ldots, \beta_k)$.

Let $\mathscr{P}$ be the space of all probability measures on R_1. Ferguson defined a Probability measure called a Dirichlet measure for a random Probability measure P taking values in $\mathscr{P}$. (To be more rigorous, we should also define the σ field in $\mathscr{P}$, but we shall avoid going into such details.) Ferguson defined the Dirichlet measure with parameters α and μ, where $\alpha > 0$ and μ is a probability measure on R_1, as follows: for every finite partition $\mathscr{A}$, $P(\mathscr{A})$ has the finite dimensional Dirichlet distribution with parameters $\mathscr{D}[\alpha\mu(A_1), \ldots, \alpha\mu(A_k)]$. In particular the distribution of $P(A)$ is a Beta distribution with parameters $[\alpha\mu(A), \alpha\mu(A^c)]$. It takes some more mathematical machinery to show that such a Dirichlet measure exists, but again we will not go into this here. The Dirichlet measure above will be denoted in symbols by $\mathscr{D}(\alpha, \mu)$.

Many interesting properties of Dirichlet measures are known. These are easy to derive from the representation of Dirichlet measures given by Sethuraman (1994) which is described in the next paragraph. The Dirichlet measure $\mathscr{D}(\alpha, \mu)$ gives probability one to the class of all discrete distributions in R_1 even if μ is a continuous distribution. The expected value and variance of $P(A)$ are $\mu(A)$ and $\mu(A)\mu(A^c)/(\alpha + 1)$. The expected value and variance of$\int f dP$ is $\int f d\mu$ and $(\int f^2 d\mu - (\int f d\mu)^2)/(\alpha + 1)$.

An easy constructive definition of a Dirichlet measure was announced in Sethuraman and Tiwari (1982) and proved in more detail in Sethuraman (1994). Consider independent random variables $Y_1, Y_2, \ldots, \theta_1, \theta_2, \ldots$ where the Y's are identically distributed (*iid*) with common distribution μ and the θ's are identically distributed with a common Beta distribution with parameters 1 and α. Define

$$p_1 = \theta_1, \quad p_k = \theta_k \prod_{j=1}^{k-1} (1 - \theta_j) \qquad [1]$$

$$P(A) = \sum_k p_k I(Y_k \in A) \qquad [2]$$

where for any event B, the indicator function $I(B) = 1$ if B occurs and $I(B) = 0$ otherwise. Clearly, P is a random discrete probability measure putting random probability mass p_k at Y_k. Its distribution is the Dirichlet measure $\mathscr{D}(\alpha, \mu)$.

Let $X_1, X_2, \ldots$ be random variables such that, given P, they are i.i.d. with common distribution P. Let F_n be the empirical distribution of $X_1, X_2, \ldots, X_n$, that is, $F_n(x) = \frac{1}{n}\sum_1^n I(X_i \leq x)$. The conditional distribution of P, given the sample $X_1, X_2, \ldots, X_n$, was shown by Ferguson (1973) to be the Dirichlet measure with parameters $(\alpha + n, \mu_n)$, where

$$\mu_n = \frac{\alpha}{\alpha + n}\mu + \frac{n}{\alpha + n}F_n \qquad [3]$$

Blackwell (1973) and Blackwell and MacQueen (1973) give alternative ways of defining Dirichlet measures and establishing the above result on the posterior distribution.

We will now briefly describe some popular uses of the Dirichlet prior in nonparametric problems. Suppose that we have data consisting of $X_1, \ldots, X_n$ which, given P, are independent and identically distributed with common probability distribution P. Suppose that we want to estimate P. The frequentist's usual estimator is $F_n(X) = \frac{1}{n}\sum_1^n I(X_i \leq x)$ the empirical distribution of the data $X_1, \ldots, X_n$.

A Bayesian would place a Dirichlet prior $\mathscr{D}(\alpha, \mu)$ as a prior distribution for P. The measure μ would represent his average guess of the unknown P and α would represent his measure of confidence in this guess, with large values of α denoting more confidence. Then the posterior distribution of P is the Dirichlet measure $\mathscr{D}(\alpha + n, \mu_n)$ where μ_n is given by eqn [3]. Under squared error loss, the Bayes estimate of any function $g(P)$ is simply its expectation of $g(P)$ under this posterior distribution. Thus the Bayes estimates of P, $P((-\infty, x])$ and $\int f(x)dP(dx)$ are μ_n, $\mu_n((-\infty, x])$ and $\int f(x)\mu_n(dx)$, respectively. Under absolute value of error loss function, the Bayes estimate of the median of P is the median of μ_n. The expected Bayes loss of all these estimates are obtained in Ferguson (1973). To summarize these results in simple terms, the Bayes estimate of P is μ_n which is a convex linear combination of the parameter μ of the prior distribution and the empirical distribution function F_n of the observed data, where the weight given to μ, the prior guess, goes to zero as the sample size of the data increases, a fact that agrees well with intuition. Susarla and Van Ryzin (1976) obtain Bayes estimates of P when the observations are censored by independent censoring variables, which we discuss later. For more examples of Bayes estimates of other functionals see Yamato (1975), Hollander and Korwar (1982), Zalkikar et al. (1986), Wells and Tiwari (1989), and Lu et al. (1994).

The influence of the parameter μ in the prior distribution goes to zero as n gets large and the Bayes estimate is close to F_n. In fact, if one were to formally put the parameter α of the prior distribution to be zero, then the Bayes estimate is F_n; this has

led some researchers to refer to α as the prior sample size. There is a difficulty with this notion. The prior distribution is not defined if $\alpha = 0$. However, the prior distribution converges to a proper prior distribution as $\alpha \to 0$ and μ is held fixed. This limiting prior corresponds to a random degenerate distribution, and as such will not be an acceptable prior distribution for Bayesian problems (see Sethuraman and Tiwari, 1982). In spite of this, many researchers check to see if they get familiar frequentist estimators when $\alpha \to 0$.

This summarizes the first results concerning applications of Dirichlet measures for Bayesian analysis in one-sample problems. Similar results which have wider applicability have been obtained for two-sample problems, Bayesian density estimation, censored samples, reliability, point processes, etc.

There has been work in finding prior distributions which are more general than Dirichlet measures, like measures that concentrate on absolutely continuous distributions, or distributions with increasing failure rate, and so on. The problem of constructing a random probability distribution requires a clear understanding of the structure of a probability measure.

Consider partitioning the whole space into two sets A_0, A_1, and then partitioning each of these as A_{00}, A_{01} and A_{10}, A_{11}, respectively. At the nth stage we will have 2^n sets A_{t_n}, where t_n is an n-vector of zeros and ones. The set A_{t_n} will be partitioned as $A_{t_n,0}$, $A_{t_n,1}$, and we will have 2^{n+1} sets at the $(n+1)$th stage, and so on. Suppose the partitioning sets from all stages, namely $\{A_0, A_1, \ldots, A_{t_n}, \ldots\}$, generate the Borel σ-field $\mathscr{B}$ in R_1. Any probability measure P on R_1 gives rise to the quantities $[u_e = p(A_1),\ u_0 = P(A_{01}|A_0),\ u_1 = P(A_{11}|A_1), \ldots,\ u_{t_n} = P(A_{t_n1}|A_{t_n}), \ldots]$ all of which lie between zero and one and conversely any sequence on numbers $(u_e, u_0, u_1, \ldots, u_{t_n}, \ldots)$ in [0, 1] will give rise to a unique probability measure P on R_1. Furthermore, the range of each u_{t_n} is unrestricted. Thus it is easy to assign probability distributions to (u_{t_n}). Any such distribution induces a probability measure on the space of probability measures on R_1 and can serve as a prior distribution in nonparametric problems. If we assume that the u's are independent with u_{t_n} having a Beta distribution with parameters $[\alpha\mu(A_{t_n1}),\ \alpha\mu(A_{t_n0})]$, then Blackwell (1973) showed that the resulting distribution for P is $\mathscr{D}(\alpha, \mu)$. By choosing other distributions for the u's one can obtain prior distributions that concentrate on absolutely continuous distributions, distributions which are symmetric, unimodal, or have increasing failure rate, etc.

Another way to introduce prior distributions for P arises from the fact that, when the distribution of $X_1, X_2, \ldots$ are i.i.d. P given P, the distribution of $X_1, X_2, \ldots$ is exchangeable. In fact, from De Finetti's theorem, if $X_1, X_2, \ldots$ is exchangeable, then there is a function P of $X_1, X_2, \ldots$, which is a random probability measure, and given this P, the $X_1, X_2, \ldots$ become i.i.d. P. The distribution of this P is a prior distribution on the space of all probability measures on R_1. Thus every sequence of exchangeable random variables corresponds to a prior distribution on the space of probability measures. Using this approach, Blackwell and MacQueen (1973) showed that the Pólyaurn scheme produces an exchangeable sequence of random variables leading to Dirichlet measures. Exchangeable distributions are usually derived as i.i.d. random variables with a common P having a prior distributions rather than vice versa, and so this method has not yielded a rich variety of prior distributions. There is, however, a mathematical beauty in this method.

Computational Methods in Nonparametrics: Bootstrap and Gibbs Sampling

Two methods, namely the bootstrap (*see* Resampling Methods of Estimation) and Gibbs sampling methods (*see* Monte Carlo Methods and Bayesian Computation: Overview), have proved very successful in handling a multitude of inference problems that could not be handled before since the various distributions needed for inference are generally mathematically intractable. These sampling methods replace the mathematical machinery with computational methods to obtain approximations for large classes of distributions. A lot of ingenuity still has to go into each situation to make these computational methods effective. Much theory has also been developed to prove that these computational methods work when the number of iterations and sample sizes become large, but we will not describe those developments here. We will give a general introduction and describe some examples.

Let $X_1, \ldots, X_n$ be iid with common distribution P. Let $F_n = \frac{1}{n}\sum_1^n I(X_i \le x)$ be the empirical distribution function which is an estimate of P. Suppose that we wish to estimate the parameter $\theta = g(P)$, where $g(P)$ is some function of P. The population mean $\theta = \int xP(\mathrm{d}x)$ is an example of such a parameter. An obvious estimate of this θ would be $g(F_n)$. One would also like to give the precision of this estimate, namely the standard error of this estimate. This can be done using the bootstrap. The bootstrap method says that if we draw a sample $X_1^*, \ldots, X_n^*$ of size n from F_n (i.e., a simple random sample of size n with replacement from the originally observed sample) and compute its empirical distribution function F_n^* then $g(F_n^*)$ bears the same relation to $g(F_n)$ as $g(F_n^*)$ bears to $g(P)$. If we repeat this procedure K times where K is large, then the standard deviation of the K values of $g(F_n^*)$ will be an estimate of the precision of the estimate $g(F_n^*)$. This, in a nutshell, is the bootstrap method in its simplest form, as introduced by Efron (1979). The asymptotic accuracy of the bootstrap has been established among others by Bickel and Freedman (1981) and Singh (1981). This method can apply to parametric as well as nonparametric problems. We will illustrate the bootstrap in two nonparametric problems below.

Testing for Concordance

Kendall's τ is a measure of concordance, namely the tendency of two random variables X and Y to increase or decrease together. It possesses the desirable property that it is invariant under monotone increasing transformations of X and Y and so depends only on the rankings and not the exact magnitudes of X and Y. Let (X, Y) have a joint distribution H. Let $I(\cdot)$ stand for the usual indicator function. Define the concordance between a pair of vectors (x_1, x_2) and (y_1, y_2) as

$$\begin{aligned} C[(x_1, x_2, (y_1, y_2)] &= I[(x_2 - x_1)(y_2 - y_1) > 0] \\ &\quad - I[(x_2 - x_1)(y_2 - y_1) < 0] \end{aligned}$$

which is equal to 1 if $(x_2 - x_1)$ and $(y_2 - y_1)$ are of the same sign, -1 if they are of opposite signs and 0 if either $x_1 = x_2$ or $y_1 = y_2$. The population value of τ is defined by

$$\tau = E\{C[(X_1, X_2), (Y_1, Y_2)]\} \quad [4]$$

Note that if X and Y are independent then $\tau = 0$. Consider a sample $(X_n, Y_n) = [(X_1, Y_1), \ldots, (X_n, Y_n)]$ which is iid with common distribution function $H(x, y)$. A natural sample estimate of τ_n of τ is given by

$$\tau_n = \frac{2}{n(n-1)} \sum_{1 \le i < j \le n} C\left[\left(X_i - X_j\right), \left(Y_i - Y_j\right)\right] \quad [5]$$

The above definition can be simplified if there are no ties in the data. The statistic τ_n can also be recognized to be a U-statistic and so one can derive its asymptotic distribution, see for instance Hoeffding (1948), under both the null and alternative hypotheses. However, the asymptotic distribution of τ_n depends on the joint distribution $H(x, y)$ and the variance should be estimated to produce confidence intervals for τ. We give below the details of a simple use of the bootstrap to solve this problem and illustrate it with a numerical example taken from Hollander and Wolfe (1999: Section 8.1).

Let $H_n(x, y)$ be a joint distribution that places mass $1/n$ at each of the observations $(X_1, Y_1), \ldots, (X_n, Y_n)$. This H_n is the empirical distribution function of the bi-variate sample. Let $(X_n^*, Y_n^*) = [(X_1^*, Y_1^*), \ldots, X_n^*, Y_n^*]$ be a sample of size n from H_n and let τ_n^* be the τ-statistic computed from this sample. By repeating this K times, one gets K values of τ_n^*. Let a_n, b_n be the $B\alpha$-largest and $B(1 - \alpha)$-largest values of these K values of τ_n^* arranged in increasing order. The interval $[a_n, b_n]$ is an approximate $1 - 2\alpha$ confidence interval for τ. Standard theorems show that the confidence level of this confidence interval converges to $1 - 2\alpha$ as $K, n \to \infty$.

Rasekh et al. (1970) wish to evaluate the relative importance of factors contributing to tuna quality, in particular the importance of the Hunter L value factor. A small subset of the data is given in **Table 1** (see also Hollander and Wolfe, 1999).

The value of τ_n from this sample is $4/9 = 0.444\,4$ and this is an estimate of the population value of τ. This shows that there seems to be a positive dependence between the Hunter L value and tuna quality. A confidence interval for τ can now be obtained by the use of the bootstrap. One thousand samples were generated by the bootstrap sampling scheme from the given data using a program written in the statistical package S-Plus. The 90% confidence interval for τ was found to be $[-0.027\,8, 0.750\,0]$, the interval containing 90% of the 1000 values of τ_n generated by the bootstrap. Since zero falls in this interval, we cannot rule out that the Hunter L value has no influence on tuna quality, if we use a 90% confidence interval as a two-sided test of independence with type-I error probability approximately 10%.

Testing Independence

Suppose that we want to test that two random variables X and Y are independent. Consider a sample $(X_n, Y_n) = [X_1, Y_1, \ldots, (X_n, Y_n)]$ which is iid with common distribution function $H(x, y)$ with marginal distribution functions $F(x)$ and $G(y)$. We wish to test the hypothesis of independence, namely that

$$H(x, y) = F(x)\, G(y) \quad [6]$$

for all x, y. One may restate this problem as asking whether the joint distribution given by taking the marginals to be independent fits the actual distribution very closely; in this sense this problem can be considered as a goodness-of-fit problem. A standard test is to reject for large values of the statistic

$$T_n = T_n(X_n, Y_n) = \sup_{x,y} |H_n(x, y) - F_n(x) G_n(y)| \quad [7]$$

where $H_n(x, y)$, $F_n(x)$, $G_n(y)$ are the joint empirical and marginal empirical distributions. How should we choose the critical value for T_n?

The statistic T_n is distribution-free under the null hypothesis, if the distributions are continuous. The bootstrap implementation, which is valid even when the distributions are not continuous, proceeds as follows. Notice that $F_n(x)$ and $G_n(y)$ are the sample estimates of the marginal distribution functions. Under the null hypothesis, $F_n(x)G_n(y)$ will be an estimate of the joint distribution function. Thus one collects a sample $(X_n^*, Y_n^*) = [(X_1^*, Y_1^*), \ldots, (X_n^*, Y_n^*)]$ from the distribution $F_n(x)$ $G_n(y)$ and computes the statistic $T_n^* = T_n(X_n^*, Y_n^*)$. This is repeated K times. Let $c_n(\alpha)$ be the $K\alpha$-th largest value of these T_n^*s arranged in increasing order. This $c_n(\alpha)$ is taken to be the critical value at level α and the null hypothesis is rejected if T_n is larger than $c_n(\alpha)$. This implementation of the bootstrap is described and illustrated in two articles by Romano (1988, 1989), where it is shown that this bootstrap test is consistent, if $K, n \to \infty$.

Table 2 gives the data considered by Clark et al. (1961) in a study concerned with the relationship of scores on various psychological tests and certain physical characteristics of 13 nonidentical male twins (see Hollander and Wolfe, 1999: Section 8.1).

The value of the T_n given by eqn [7] for the data is 0.177 5. The bivariate distribution in which X and Y are independent and have the marginal distributions given by the above data was constructed. One thousand bivariate samples were generated from this distribution and the 5% upper cut-off point of the T_n statistic calculated from these 1000 samples were found to be 0.189 3. This shows that the scores of the two twins can be concluded to be independent at the 5% level.

Gibbs Sampling

Gibbs sampling is a computational method to calculate distributions which are intractable by mathematical means. Suppose that we wish to obtain samples from a joint distribution H of a bivariate random variable (X, Y) or just want to evaluate $\int g(x, y)\mathrm{d}H(x, y)$for some function $g(x, y)$. This may be difficult because the joint distribution H is quite complicated or only indirectly defined. Suppose that the conditional distributions $Q(x|y) = P(X \leq x|Y = y)$ and $R(y|x) = P(Y \leq y|X = x)$ are known sufficiently well enough to generate observations from them. Then we can proceed as follows. Let (X_0, Y_0) be arbitrary. Generate X_n. from the distribution $Q(\bullet|Y_{n-1})$ and Y_n from the distribution $R(\cdot|X_n)$, $n = 1, \ldots, N$. One can check that $(X_0, Y_0), (X_1, Y_1), \ldots$, is a Markov chain with a transition function for which H is an invariant distribution. If this transition function satisfies some mild conditions, then this Markov chain converges in one of several senses to H, and so, for large N, one can take

$$\frac{1}{N}\sum I[(X_i, Y_i) \in A] \quad \text{and} \quad \frac{1}{N}\sum g(X_i, Y_i)$$

to be approximations to $H(A)$ and $\int g(x, y)\ \mathrm{d}H(x, y)$. If the convergence is stronger, then one can take (X_N, Y_N), as approximately having distribution H. This is the essence of the Gibbs sampler of which there are many other variations. See Gelfand and Smith (1990), Tierney (1994) (for more details *see* Monte Carlo Methods and Bayesian Computation: Overview).

We will now illustrate the Gibbs sampler in a nonparametric censoring problem. Suppose that, given F and G, $X_1, \ldots, X_n, Y_1, \ldots, Y_n$ are independent with $X_1, \ldots, X_n$ iid with common distribution F and with $Y_1, \ldots, Y_n$ iid with common distribution G. We will assume that the distribution functions F and G are continuous functions. Suppose that we observe only $Z_i = \min(X_i, Y_i)$, $\delta_i = I(X_i \leq Y_i)$, $i = 1, \ldots, n$; Z_i is the censored value of X_i if $\delta_i = 0$ and the actual value of X_i if $\delta_i = 1$.That is, sometimes we observe an X_i and at other times we just know that $X_i \in (Y_i, \infty)$. The problem is to estimate $F(x)$ or the survival function $\overline{F}(x) = 1 - F(x)$. A Bayesian approach would be to put a prior on (F, G) and look at the conditional distribution of F given the data. Assume that under the prior distribution, F and G are independent and that F has a Dirichlet measure $\mathscr{D}(\alpha\mu)$. The distribution of G will be irrelevant and it can be shown in this Bayesian problem that we can consider the values of $Y_1, \ldots, Y_n$ as constants (see Lo, 1993 for instance). We can rearrange the sample so that $Z_1 = X_1, \ldots, Z_r = X_r, Z_{r+1} = Y_{r+1}, \ldots, Z_n = Y_n$ where r is the number of uncensored X's. The number of censored observations is $m = n - r$. This means the sample consists of $X_1, \ldots, X_r$ and the information $X_i \in A_i$, $i = r + 1, \ldots, n$, where $A_i = (Y_i, \infty)$, $i = r + 1, \ldots, n$. The Bayesian posterior distribution is the conditional distribution of F given the data. We will show now how Gibbs sampling can help us to simulate from this distribution after we describe earlier work on a closed form expression for the Bayes estimate of F.

The Bayes estimate of F is the expected value of F under this posterior distribution. This can be obtained without evaluating the complete posterior distribution as shown in Susarla and Van Ryzin (1976). Let $N_n(A) = \sum_1^n I(Z_i \in A)$ be the number of observations (censored or not) that fall in A. Let $Z_1^* < Z_2^* < \ldots < Z_m^*$ be the distinct values among the censored observations $Z_{r+1}, \ldots, Z_n$. Let λ_k be the number of censored observations equal to Z_k^*, $k = 1, \ldots, m$. Then the Bayes estimate of $\overline{F}(x)$ as obtained by Susarla and Van Ryzin (1976) is given by

$$\widehat{\overline{F}}_n(x) = \frac{\alpha\mu(x, \infty) + N_n(x, \infty)}{\alpha\mu(0, \infty) + n} \text{"times} \prod_{j=1}^{m}\left[\frac{\alpha\mu\left(\left[Z_j^*, \infty\right)\right) + N_n\left(\left[Z_i^*, \infty\right)\right)}{\alpha\mu\left(\left[Z_j^*, \infty\right)\right) + N_n\left(\left[Z_j^*, \infty\right)\right) - \lambda_j}\right] \quad [8]$$

for $Z_l^* \leq x < Z_{l+1}^*$, $l = 0, 1, \ldots, m$ where we set $Z_0^* = 0$, $Z_{m+1}^* = \infty$. This estimate converges to the standard Kaplan–Meier frequentist estimate (Kaplan and Meier, 1958) as $\alpha \to \infty$.

A full Bayesian analysis will require the posterior distribution of F. This can be accomplished in this problem through Gibbs sampling. This will also yield a way to obtain the posterior estimate of the survival function, by computational methods, which then can be compared with the exact estimate of Susarla and Van Ryzin given in eqn [8]. The conditional distribution of F given $X_1, \ldots, X_r$ (the observed X's) is $\mathscr{D}(\alpha + r, \mu_r)$ where μ_r is as defined in eqn [3] with $n = r$. Let F, $X_{r+1}, \ldots, X_n$ be such that F has distribution $\mathscr{D}(\alpha + r, \mu_r)$ and given F, let $X_{r+1}, \ldots, X_n$ be iid F. The posterior distribution is the conditional distribution of F given $X_i \in A_i$, $i = r + 1, \ldots, n$.

It is clear that we do not know the precise values of $X_{r+1}, \ldots, X_n$, but we know only that $X_i \in A_i$, $i = r + 1, \ldots, n$. The standard theory of Dirichlet distributions shows that the conditional distribution $Q(F|X_r, \ldots, X_n, \text{data})$ of F given $X_r, \ldots, X_n$ and the data is equal to $\mathscr{D}(\alpha + n, \mu_n)$ where μ_n is given by eqn [3]. We also know that the conditional distribution $R(X_{r+1}, \ldots, X_n|\ F, \text{data})$ of $X_{r+1}, \ldots, X_n$ given F and the data, is just that of independent random variables with distributions $F_{A_{r+1}}, \ldots, F_{A_n}$ where for any set A, F_A represents that distribution F restricted to the set A. Thus, in the joint distribution of F and $(X_{r+1}, \ldots, X_n)$ given the data, we know the two conditional distributions.

Table 3 Exact and computational Bayes estimates of $F(x)$ based on Kaplan and Meier Data ($\alpha = 8, \mu = exponential with scale parameter 0.12)

This provides the necessary parts to carry out Gibbs sampling. After simulating an observation $(F, X_{r+1}, \ldots, X_n)$ from the joint distribution of F and $(X_{r+1}, \ldots, X_n)$ given the data, we can retain just the F which then can be considered as an observation from the posterior distribution.

There is a special difficulty in this example of Gibbs sampling. How does one generate a distribution F from a Dirichlet measure? This F is not a simple as a real valued random variable. The constructive definition of a Dirichlet measure given in Sethuraman (1994) will be useful here. Suppose that at stage 0 of Gibbs sampling, we start with arbitrary or well chosen $F^0, X^0_{r+1}, \ldots, X^0_n$. Let $\mu^0_n = \frac{1}{n}[\alpha\mu + \sum_1^r \delta_{X_i} \sum_{r+1}^n \delta_{X^0_i}]$. Then F^1 has to be generated from $\mathscr{D}(\alpha + n, \mu^0_n)$. Thus we may take $F^1(x) \sum_k^\infty p_k I(W_i \le x)$, where $W_1, W_2, \ldots$ are iid μ^0_n and the p_ks are given by eqn [1] based on independent $\theta_1, \theta_2, \ldots$ which are iid Beta $(1, \alpha + n)$. This is an infinite sum and cannot be computed exactly. In fact, we will avoid generating this F^1 in a precise fashion and go to the next step of generating $(X^1_{r+1}, \ldots, X^1_n)$ as iid observations from this F^1 and satisfying the restrictions $X^1_i \in A_i,\ i = r+1, \ldots, n$. The constructive definition of Sethuraman (1994) states that $X^1_{r+1}, \ldots, X^1_n$ can be taken to be $W_{I_{r+1}}, \ldots, W_{I_n}$ where $I_{r+1}, \ldots, I_n$ are drawn iid from the random discrete distribution $\{p_k, k = 1, \ldots\}$. Thus one first generates a sufficiently large vector $W_1, \ldots, W_N$ which are iid μ^0_n. The random index I_{r+1} is then generated as min $\{j : \sum_1^j p_i \ge U\}$, where U is a uniform random variable on [0, 1]. This means that we will need to generate only a finite (though random) number of p_is to generate I_{r+1}. If the value $X^1_{r+1} = W_{I_{r+1}}$ is not in A_{r+1} we will repeat this step until $X^1_{r+1} \in A_{r+1}$. This will give us X^1_{r+1}. We continue until the remaining $X^1_{r+2}, \ldots, X^1_n$ are generated. In a similar fashion, we generate $(F^M, X^M_{r+1}, \ldots, X^M_n)$ for $M = 1, 2, \ldots, K$, noting that at each step we did not have to calculate the infinite series for F^M. The expected value of F^M, namely μ^M_n or the average of μ^M_n over several such runs, will be the computational Bayes estimate of μ. This computational method is described in Doss (1994). A result from Athreya et al. (1994) can be used to justify that the Gibbs sampler converges.

We illustrate the above with the following example taken from Doss (1994). Kaplan and Meier (1958) presented the following data on lifetimes on eight subjects in which four were not fully observed, that is, were censored (indicated with a+):

$$0.8,\ 1.0+,\ 2.7+,\ 3.1,\ 5.4,\ 7.0+,\ 9.2,\ 12.1+$$

The exact and computational Bayes estimates based on these data are very close to one another as can be seen from Table 3. For comparison purposes, the original standard frequentist estimate of Kaplan and Meier (KM) is also presented in the same table. As expected, the Bayesian estimate is smoother and varies over a wider range.

One can extend the above to the case where F is specified to come from a family $H(x - \theta)$, where H has a Dirichlet prior, and one can place an independent prior distribution on the real valued parameter θ. Doss (1994) extends the above Gibbs sampling method for this more general prior and obtains the posterior distribution and the Bayes estimate of θ. An illustrative numerical example can also be found in that paper.

The above constitute only a typical example of the use of Gibbs sampling in nonparametric Bayesian problems. There have been many interesting applications of Gibbs sampling; for some early references see Escobar (1994, 1995), and Escobar and West (1995).

Conclusion

Nonparametric methods have established themselves not just as competitors to parametric methods, but actually as being superior to them under certain circumstances, while still providing valid and robust procedures. Incorporating prior information and expert knowledge into nonparametric procedures becomes the next important advance in statistical methodology. In the first section we described various ways of defining Dirichlet measures which can serve as prior distributions in nonparametric problems. It turns out that the actual Bayesian solution to a particular nonparametric problem may not be in a simple closed form and therefore may require some intensive computing. The bootstrap method and Gibbs sampling represent two such computational procedures. We have presented two examples of the bootstrap: to test for concordance and to test for independence, and have illustrated the Gibbs sampler to estimate the survival distribution when censoring is present.

Abstract

Nonparametric methods are procedures of statistical inference for models without precise assumptions about the distribution of the sample. A typical case is the two-sample test problem, where samples from two populations are observed, and the hypothesis that two populations have the same distribution is tested. Various types of test procedures have been proposed, their distributions under the hypothesis are obtained from the permutation distribution, that is, the conditional distribution given the set of values of the two samples combined. In most cases, small sample exact distribution is complicated to compute, but asymptotic approximations based on the central limit theorem for the permutation distribution can be applied. Also, power of the tests can be calculated from the normal approximation of the test statistic under the contiguous alternatives, and the relative efficiency of the test is defined and calculated. There are classes of tests with high relative efficiency. Also optimal parametric test can be regarded as approximate nonparametric tests in this context. Similar theory obtains for other classes of nonparametric tests and for interval estimation procedures derived from them.

Nonparametric methods are methods of statistical inference without precise assumptions on the shape of probability distribution of the observations. More precisely, a statistical model where the joint probability distribution is determined by a finite set of real parameters, or a finite dimensional real vector is called parametric, and methods of statistical inference without assuming a parametric model, is called nonparametric. Nonparametric methods, and especially nonparametric tests, have a long history. They can be traced back to the nineteenth century. Before 1940, rank correlation, rank sum tests, and permutation tests were known. However, they were often considered as merely 'quick and simple methods, substituting for more exact' procedures like t-tests, analysis of variance, etc., which were thought to be tedious.

The true nature of nonparametric methods has come to be understood since the 1950s and some of the nonparametric procedures have been found to have not only validity irrespective of the shape of underlying distribution, but also to have rather high efficiency under standard cases such as the normal distribution. Hence they have a high degree of robustness. Although the computation of the distribution of nonparametric statistics is now not difficult with modern computers, small sample distributions are usually complicated. Though they may not be difficult to compute for specific cases, it is not easy to understand their general features. Hence asymptotic theory is called for, and gives the result not for only null cases but also for alternative cases, leading to the definition and calculation of the relative efficiency of the procedures.

The term nonparametric is sometimes used in a different sense. Thus nonparametric regression usually means not that the distribution of the error is unspecified, but that the form of the regression function is not specified by a finite number of parameters. However, such problems belong to a different area of theory and hence are not dealt with in this article. Basic aspects of the asymptotic nonparametric theory are expounded for some basic cases. There are two main nonparametric procedures: (a) testing hypotheses, and (b) interval estimation.

Two-Sample Tests

Among nonparametric procedures, the most common is the nonparametric hypothesis testing, where the hypothesis to be tested is expressed in a nonparametric framework. Simplest and most often appearing in practical applications is the so-called two-sample problem where it is required to test the equality of two probability distributions. More precisely, we have two sets of sample observations $\mathbf{X} = (X_1, X_2, \ldots, X_n)$ and $\mathbf{Y} = (Y_1, Y_2, \ldots, Y_m)$ where X_is and Y_js are real random variables distributed according to continuous distributions, F and G respectively, and it is required to test the hypothesis that the two distributions are identical, that is

$$H : F \equiv G$$

A nonparametric test function φ is a measurable function of $\mathbf{X}$ and $\mathbf{Y}$, satisfying the conditions that

$$0 \leq \phi(\mathbf{X}, \mathbf{Y}) \leq 1,$$

and

$$E(\phi(\mathbf{X}, \mathbf{Y}) | F \equiv G) \leq \alpha \quad \text{for all possible } F$$

When $E(\varphi | F \equiv G)$, which is called the size of the test, is always equal to α, the test is called a similar, or exactly nonparametric test.

When F is assumed to be continuous, there is a general method to derive similar tests. We define the order statistics $\tilde{X} = (X_{(1)} < X_{(2)} < \ldots < X_{(n)})$ and $\tilde{Y} = (Y_{(1)} < Y_{(2)} < \ldots < Y_{(m)})$ where $X_{(i)}$s are values of X_is arranged according to their magnitudes, and $Y_{(j)}$'s are ordered values of Y_js. Given $\tilde{X}$ and$\tilde{Y}$, the conditional distributions of X and Y are independent of F and G. Hence the pair of $\tilde{X}$ and $\tilde{Y}$ is a sufficient statistic, and we may consider φ as the function of $\tilde{X}$ and $\tilde{Y}$ (Fraser, 1957, Lehmann, 1959). Now we also define the combined order statistics $Z=(Z_1<Z_2<\ldots<Z_{n+m})$ where Z_ks are either one of the X_is or

one of the Y_js, thus $\tilde{Z}$ is the set of values of $\tilde{X}$ and $\tilde{Y}$ combined and ordered. Then we have

$$P\{\tilde{X} = (Z_{i_1}, Z_{i_2}, \ldots, Z_{i_n}) | \tilde{Z} = (Z_1, Z_2, \ldots, Z_{n+m})\} = \frac{1}{{}_{n+m}C_n}$$

that is the conditional probability that the values of $\tilde{X}$ being equal to any combination of n values in $\tilde{Z}$ is always the same and equal to $(1/{}_{n+m}C_n)$, whatever the probability distribution $F \equiv G$ be, provided only that F is continuous so that no two values of Xs and Ys are equal.

Then if the test function satisfies the condition that

$$E(\phi(\tilde{X}, \tilde{Y}) | \tilde{Z}) \equiv \alpha \qquad [1]$$

that is, the conditional expectation of α given the combined order statistic $\tilde{Z}$ is always equal to α under the hypothesis, it follows that

$$E(\phi(\tilde{X}, \tilde{Y}) | F \equiv G) = \alpha \quad \text{for all } F = G \qquad [2]$$

hence φ is a similar test (Lehmann, 1959). Conversely if φ is similar, it is proved that (2) must hold for almost all values of $\tilde{Z}$.

Test Statistic

Various similar test functions can be constructed in the following manner. Let t be a function of n values depending on the combined order statistics $\tilde{Z}$. Then the conditional distribution given $\tilde{Z}$ of $T = t(\tilde{x})$ can be computed from (2). Choose a constant c and also $0 \le r \le 1$, and define

$$\phi(\tilde{x}) = \begin{cases} 1 & \text{if } t(\tilde{x}) > c \\ \mathrm{r} & \text{if } t(\tilde{x}) = c \end{cases}$$

so that $E(\phi(\hat{x}) | F \equiv G) = \alpha$. Thus we get a similar nonparametric test procedure.

There are two types of such functions. The first is a function whose marginal distribution is independent of the distribution F under the hypothesis. The rank of $x_i = x_i$ among $\tilde{Z} = (Z_1, Z_2, \ldots, Z_{n+m}) Z_1 < Z_2 < \cdots < Z_{n+m}$ is defined to be R_i if x_i is equal to Z_{Ri}. If t depends only on the ranks of X_is the distribution of $T = t(X) = t(R_1, R_2, \ldots, R_n)$ is clearly independent of F. By proper choice of t, most common nonparametric tests are obtained. The simplest one is the rank sum $T = \sum_{i+1}^{n} R_i$, and the hypothesis is rejected when T is either too large or too small.

The weighted rank or rank score sum test is a generalization of the rank sum test, defined by the criterion function $T = \sum_{i=1}^{n+m} c(R)_i$ where $c(R)$ is a function of the rank R. The score function $c(R)$ is often defined to be equal to the expectation of the R-th order statistic on the sample of size $n+m$ from some distribution. For example, one can take $c(R) = \xi_{R|n+m}$, the expectation of the R-th order statistics in the sample from the standerd normal distribution, or $c(R) = \frac{1}{R}$, the same from the exponental distribution. A more simple function is

$$c(R) = \begin{cases} +1 & \text{for } R \gtrless \dfrac{n+m+1}{2} \\ 0 & \text{for } R = \dfrac{n+m+1}{2} \end{cases}$$

which is called the median test. Sometimes a non-monotone function is used such as $c(R) = |\xi_{R(n+m)}|$.

Consider any statistic $T = t(X_1, X_2, \ldots, X_n)$. Its conditional distribution given $\tilde{Z}$ is called the permutation distribution of T. Then a nonparametric test can be obtained by using T as test criterion with the critical point calculated from the permutation distribution.

Using the idea of permutation tests every parametric test statistic can also be used as the second type of nonparametric test criterion. For example, if F and G are both normal distributions with possibly different means but with common variance, the best (in various senses) test statistic is the t-statistic defined as

$$T = \sqrt{\frac{nm}{n+m}} \frac{\tilde{X} - \tilde{Y}}{S}$$

where

$$S^2 = \frac{\sum_{i=1}^{n} (X_i - \overline{X})^2 + \sum_{j=1}^{m} (Y_i - \overline{Y})}{(n+m-2)}$$

T is distributed according to the t-distribution with degrees of freedom $n+m-2$ under the normal hypothesis. But we can also consider the permutation distribution of T given $\tilde{Z}$. It can be shown that given $\tilde{Z}$, the statistic T is equivalent to $\tilde{X}$, the mean of the first sample.

Asymptotic Distribution Under the Hypothesis

The conditional distribution of any statistic $t(\tilde{X})$ given $\tilde{Z}$ is difficult to calculate in general, and so its asymptotic approximation plays an important role. A basic result under the hypothesis is the following (Fraser, 1957).

Theorem: Under some regularity conditions, the conditional distribution of $T = (1/\sqrt{nv})(\overline{X} - \mu)$ approaches the standard normal distribution given $\tilde{Z} = (Z_1, Z_2, \ldots, Z_{n+m})$ when n and m tends to be large where

$$\mu = \frac{1}{n+m} \sum_{i=1}^{n+m} Z_i, \quad v^2 = \frac{\sum_{i=1}^{n+m} (Z_t - m)^2}{n+m-1}$$

Here the regularity condition is troublesome to express rigorously, but it requires basically that all moments of Z_i relative to v are bounded.

The theorem is readily generalized to the case when instead of $\tilde{X}$

$$\overline{g} = \frac{1}{n} \sum_{i=1}^{n} g(X_i)$$

is used. Here g is a function which may depend on $\tilde{Z}$. Then the asymptotic normality of the null distribution of rank sum statistics and various permutation statistics can be derived, and asymptotic critical values for test statistics are obtained.

Thus for example, for the rank score sum test statistic,

$$T = \sum_{i=1}^{n} c(R_i)$$

$$E(T) = \frac{n}{n+m} \sum_{r=1}^{n+m} c(r) = \overline{nc(r)}$$

$$V(T) = \frac{nm}{(n+m)(n+m+1)} \sum_{i=1}^{n+m} \left(c(r) - \overline{c(r)}^2 \right)$$

and the approximate critical points can be obtained from the normal distribution. The asymptotically conditional distribution of the usual t statistic is equivalent to its permutation distribution, and the percentage point obtained from the t distribution approximately corresponds to that of the permutation distribution (Fisher, 1935).

This fact may be interpreted to establish that the common t-test obtained under the assumption of normality is also asymptotically nonparametric, in the sense that it has approximately correct size when the sample size is large, if the two populations are the same, even if not normal.

Asymptotic Power

Although nonparametric tests are introduced to guarantee the level of the test under general conditions, it is also important to consider their power under the alternatives, consideration of which is the most important factor in choosing among many nonparametric tests. Before computers were developed, some nonparametric tests were preferred to the parametric tests because of computational simplicity, but this is no longer an issue.

In order to calculate the power we have to specify the alternative. Assume that the density function of **X** is expressed as $f_\theta(x)$ and that of **Y** as $f_0(x)$. Then the hypothesis to be tested is $H{:}\theta = 0$. Under the alternative, conditional distribution of $\tilde{X} = (X_1, X_2, \ldots, X_n)$ given $\tilde{Z}$ is expressed as

$$\begin{aligned} p(X_1 = Z_{i_1}, X_2 = Z_{i_2}, \ldots, X_n = Z_{i_n} | \tilde{Z}) \\ = c_\theta(\tilde{Z}) \prod_{j=1}^{n} f_\theta\left(Z_{i_j}\right) \end{aligned}$$

where $c_\theta(\tilde{Z})$ is a constant depending on $\tilde{Z}$. The conditional distribution of permutation test statistic can be derived from this formula.

When θ is small, that is the distribution of F_θ is close to F_0, the distribution under the alternative can also be approximated by the normal distribution. More precisely, consider a sequence of alternatives $\theta_N = \frac{\xi}{\sqrt{N}}$, and samples with

$$n = [\lambda N] \quad m = [(1-\lambda)N]$$

Where

$$0 < \lambda < 1$$

is a constant. Then we have

Theorem: (Fraser, 1957, Nikitin, 1995) Under a set of regularity conditions, the conditional distribution given $\tilde{Z}$ of

$$T = \sqrt{\frac{N\lambda}{1-\lambda}} \frac{\tilde{X} - \mu}{v}$$

approaches the normal distribution with mean ψ and variance 1 where ψ is given by

$$\psi = \xi\sqrt{\lambda(1-\lambda)} \int x \frac{\partial}{\partial\theta} f(x,\theta)|_{\theta=0} \mathrm{d}x$$

Normal approximation for other types of statistics can also be derived. Under the same set up, the asymptotically best test statistic (assuming f is known) is distributed asymptotically normal with variance 1 and mean

$$\psi^* = \xi\sqrt{\lambda(1-\lambda)}\sqrt{I(\theta)}$$

when $I(\theta)$ is the Fisher information, that is

$$I(\theta) = \int \left(\frac{\partial}{\partial\theta} \log f(x,\theta)\right)^2 f(x,\theta)\mathrm{d}x$$

The ratio $\psi^2/\psi^*2{=}e$ is called the relative efficiency of the nonparametric test, since the nonparametric test based on the sample of size N is nearly equal (in terms of power) to the best test based on a sample of size eN.

For the two-sample problem the most common model is that of shift parameter, that is, the two distributions are related by a real parameter θ so that

$$F(x) \equiv G(x-\theta)$$

Then the hypothesis corresponds to $H{:}\theta = 0$. For the general rank score test if the score function $c(R)$ can expressed as

$$c(R) = J\left(\frac{R}{n+m+1}\right)$$

where J is a continuous and smooth function with the conditions

$$\int_0^1 J(u)\mathrm{d}u = 0, \quad \int_0^1 J^2(u)\mathrm{d}u = 1$$

then the ψ above can be expressed as

$$\psi = \theta\sqrt{\lambda(1-\lambda)} \int f'(x)J(F(x))\mathrm{d}x$$

For example for the rank sum test,

$$J(u) = \frac{1}{\sqrt{12}}\left(u - \frac{1}{2}\right)$$

and

$$\begin{aligned} \psi &= \theta\sqrt{\frac{\lambda(1-\lambda)}{12}} \int f'(x)\left(F(x) - \frac{1}{2}\right)\mathrm{d}x \\ &= \theta\sqrt{\frac{\lambda(1-\lambda)}{12}} \int f^2(x)\mathrm{d}x \end{aligned}$$

from which its relative efficiency for the normal case is calculated to be equal to $3/\pi = 95$ percent.

If J is chosen to be equal to

$$J(u) = c\frac{d}{du}h_j(u), \quad \text{where } h_f(u) = f(F^{-1}(\mu))$$

the asymptotic efficiency of the rank score test is 100 percent. Thus for any specific distribution there corresponds a nonparametric rank score test which has 100 percent efficiency (Lehmann, 1959).

It is also easily proved that the permutation test derived from the best test statistic under a specified distribution is asymptotically equivalent to the best test. Since the best nonparametric test is dependent on the unknown shape of F, there is no uniformly best nonparametric test. But some information about the shape of the distribution is available from the sample, which may be utilized to choose the nonparametric test among a class of tests.

For example, the best score function $J(u)$ can be approximately constructed from the sample information. Such a method is called an adaptive procedure. There have been

proposals and theoretical results about adaptive nonparametric procedures, and there exist adaptive procedures which are 100 percent asymptotically efficient for all distributions within a rather large class (Nikitin, 1995). But these are usually very complicated, and some of them have distributions notoriously slow to converge asymptotically. Hence they are not necessarily recommendable in practical situations.

Common Nonparametric Tests

There are various problems of testing statistical hypotheses, where several types of nonparametric tests are derived in similar ways, as in the two-sample case.

Equality of Several Populations

Suppose that we have k sets of samples, each of size n_i from the population with distribution F_i. The hypothesis to be tested is $H{:}F_i \equiv F$. Let $X_i{=}(X_i, X_{i2}, \ldots, X_{in})$ be the set of the values in the sample from the i-th population, and $\tilde{Z} = (X_1, X_2, \ldots, X_k)$ conditional distribution given $\tilde{Z}$ is expressed as the total set of values of the k samples combined. Then under the hypothesis the

$$P(\tilde{x}_1, \tilde{x}_2, \ldots, \tilde{x}_k | \tilde{Z}) = \frac{n_1! n_2! \ldots n_k!}{N}$$

And nonparametric tests can be derived from this permutation distribution.

One class of such tests can be obtained from permutation distribution of the usual test criteria such as

$$F = \frac{\sum_{i=1}^{k} n_i (\overline{X}_i - \overline{\overline{X}})^2}{(k-1)S^2}, \quad S^2 = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} (X_{i,j} - \overline{X}_i)^2}{(N-k)}$$

where

$$N = \sum_{i=1}^{k_i} n_i, \quad x_i = \sum_{j=1}^{n_i} X_{i,j}/n_i, \quad \overline{\overline{X}} = \sum_{i=1}^{k} \sum_{j=1}^{n_i} X_{i,j}/N$$

or in case $n_j = n$

$$R = \max_{i,i'} \sqrt{n}(\overline{X}_i - \overline{X}_{i'})S$$

When n_is are large, $(k-1)F$ is distributed asymptotically according to the chi-square distribution with k-1 degrees of freedom and R has the same asymptotic distribution as the same as the normal studentized sample range (Randles and Wolfe, 1979).

Another class of criteria is obtained by substituting the rank score $c(R_{i,j})$ for $X_{i,j}$, where $R_{i,j}$ is the rank of $X_{i,j}$ in $\tilde{Z}$. Test criteria corresponding to the F test can be expressed as

$$T = \sum_{i=1}^{k} n_i (\overline{c}_i - \overline{\overline{c}})^2 / v^2$$

where

$$\overline{\overline{c}} = \frac{1}{n} \sum_{r=1}^{N} c(r), \quad v^2 = \frac{1}{N-1} \sum_{j=1}^{N} (c(r) - \overline{c})^2,$$

$$\overline{c}_i = \frac{1}{n} \sum_{j=1}^{n_i} c(R_{i,j})$$

The distribution of T can be approximated by the chi-square distribution. Under the alternative close to the hypothesis, the asymptotic distribution of T is expressed as a non-central chi-square distribution. More precisely, when the distribution F_i is expressed as $F_i(x) = F_{\theta i}(x)$ with real parameter and known function $F_\theta(x)$, the hypothesis expressed as $H{:}\theta_i \equiv \theta_0$, and with the sequence of samples of size $n_i = \overline{\lambda}_i N$, $\sum_{i=1}^{k} \lambda_i = 1$ under the sequence of alternatives $\theta_i = \theta_0 + \xi_i/\sqrt{N}$, the statistic T is distributed asymptotically as the non-central chi-square distribution with degrees of freedom k-1, and non-centrality $\psi = \sum_{i=1}^{k} \lambda_i \xi_i^2 \times \delta$. The constant δ depends both on the shape of the distribution and the score function $c(R)$. The relative efficiency of such tests can be defined as in the two-sample case, and with the same score function, the relative efficiency of the rank score square sum test is equal to that of the rank score test in the two-sample case (Lehmann, 1975).

Location of a Symmetric Distribution

Consider the case when $X_1, X_2, \ldots, X_n$ is a sample from a symmetric distribution centered at θ, i.e., its probability density function $f(x\text{-}\theta)$ is an even function $f(\text{-}x) = f(x)$, but otherwise is not specified. It is required to test the hypothesis $H{:}\theta{=}\theta_0$. Non-parametric test procedures can be obtained in the following way.

Define $Z_i = |X_i\text{-}\theta_0|$ and $\varepsilon_i = sgn(X_i{-}\theta_0)$. Then it is easily shown that under the hypothesis, ε_is are independent and $P(\varepsilon_i = \pm 1){=}1/2$. Let $\tilde{Z} = (Z_1, Z_2, \ldots, Z_n)$ be the set of values of Z_i. Then given $\tilde{Z}$, the conditional distribution of the statistic

$$T = t(X_1, X_2, \ldots, X_n) = t(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n, Z_1, Z_2, \ldots, Z_n)$$

is obtained. Statistics of the form $T = \sum_{i=1}^{n} \varepsilon_i c(R_i)$ have the mean and variance. Its conditional distribution can be approximated by the normal distribution when n is large.

Let R_i be the rank of Z_i. Then the test based on $T = \sum_{i=1}^{n} \varepsilon_i R_i$ is called the signed rank sum test, and more generally is called a signed rank score test statistic. The relative efficiency of such a test is defined can calculated in a completely similar way, as in the two-sample case.

Independence of Two Variables

Let (X_i, Y_i), $i = 1, 2, \ldots, n$ be a sample from a bivariate distribution. Let $F(x, y)$ be the joint distribution function. Consider the hypothesis that X and Y are independent, i.e. $F(x, y) \equiv G(x)H(y)$ assuming G and H are absolutely continuous but without any further specification.

Let $\tilde{X} = (X_1, X_2, \ldots, X_n)$ and $\tilde{Y} = (Y_1, Y_2, \ldots, Y_n)$ be the set of X-values and Y-values. Then under the hypothesis the conditional distribution of (X_i, Y_i), $i = 1, 2, \ldots, n$ given $\tilde{X} = (x_1, x_2, \ldots, x_n)$ and $\tilde{Y} = (y_1, y_2, \ldots, y_n)$ is expressed as

$$P = (X_1 = x_{i_1}, Y_1 = y_{i_1}, X_2 = x_{i_2}, Y_2 = y_{i_2}, \ldots, X_n = x_{i_n}, Y_n = y_{i_n}) = \frac{1}{n!^2}$$

for any permutation $(i_1, i_2, \ldots, i_n)$ and $(j_1, j_2, \ldots, j_n)$. This distribution is also called the permutation distribution.

Then we may define the generalized correlation coefficient

$$R = \frac{\sum_{i=1}^{n} \phi(X_i)\phi(Y_i)}{\sqrt{\sum_{i=1}^{n} (X_i)^2 \sum \phi(Y_i)}}$$

with the condition

$$\sum_{i=1}^{n} \phi(X_i) = 0, \quad \sum_{i=1}^{n} \phi(Y_i) = 0$$

Under the hypothesis given $\tilde{X}$ and $\tilde{Z}$

$$E(R) = 0 \quad V(R) = \frac{1}{n-1}$$

As n tends to infinity the distribution of R approaches the standard normal distribution (Kendall, 1948).

When $\varphi(X_i) = R_i$, R is called the rank correlation coefficient (or more precisely Spearman's ρ). When $\varphi(X_i) = X_i$, R is equal to the usual (moment) correlation coefficient. Hence it can also be interpreted as a nonparametric correlation coefficient if its permutation distribution is taken into consideration.

Equality of Multivariate Distributions

Multivariate two-sample problems can be treated in the same way as in the univariate case. Suppose that we want to test the equality of two bivariate distributions.

Let $X = \{(X_{1,1}, X_{1,2}), (X_{2,1}, X_{2,2}), \ldots, (X_{n,1}, X_{n,2})\}$ be the bivariate sample of size n from the first distribution, and $Y = \{(Y_{1,1}, Y_{1,2}), (Y_{2,1}, Y_{2,2}), \ldots, (Y_{m,1}, Y_{m,2})\}$ be the sample of size m from the second distribution. The hypothesis to be tested is that the two distributions are continuous and identical, but not otherwise specified.

Let $\tilde{Z}$ be the totality of the $n+m$ pairs of values of $\tilde{X}$ and $\tilde{Y}$. Then given $\tilde{Z}$, the conditional probability that the pairs in X are equal to the specific n pairs in $\tilde{Z}$ is equal to $1/_{n+m}C_n$ as in the univariate case. Non-parametric tests can be derived from this fact.

Define $T_1 = \sum g_1(X_{i,1})$ and $T_2 = g_2(X_{i,2})$. Then under the hypothesis the conditional distribution given $\tilde{Z}$ of (T_1, T_2) approaches a bivariate normal distribution as n and m get large (under a set of regularity conditions). Hence we can define

$$\chi^2 = s^{11}(T_1 - m_1)^2 + s^{12}(T_1 - m_1)(T_2 - m_2) + s^{22}(T_2 - m_2)^2$$

where

$$m_1 = E(T_1|\tilde{Z}), \quad m_2 = E(T_2|\tilde{Z})$$

and s^{11}, s^{12}, s^{22} are the elements of inverse of conditional variance and covariance matrix of T_1 and T_2. Then under the hypothesis χ^2 is asymptotically distributed as chi-square distribution of 2 degrees of freedom. By various choices of the function g_1, g_2, we can get bivariate versions of rank sum, rank score, etc., tests (Puri and Sen, 1971).

Nonparametric Confidence Intervals

Nonparametric test procedures can be applied to construct nonparametric confidence intervals. For example, consider the two-sample location shift model i.e., the two distributions are related as $F(x) = G(x-\theta)$. Suppose we want to construct a confidence interval $(l(X, Y), u(X, Y))$, such that

$$P\{l(X,Y) < 0 < u(X,Y\} \geq 1 - \alpha$$

for all θ and for all continuous G.

Now consider the hypothesis $\theta = \theta_0$. It is equivalent to the hypothesis that $X'_i = X_i\text{-}\theta_0$, $i = 1, 2, \ldots, n$ has the same distribution as Y_i. Hence any two-sample nonparametric test procedure can be applied to $(X'_1, X'_2, \ldots, X'_n)$ and $(Y_1, \ldots, Y_m)$. Let $\phi(\tilde{X}, \tilde{Y})$ be the test function. Then $E_{\theta_0}(\phi(\tilde{X}, \tilde{Y})) \leq \alpha$.

Now consider the class of hypotheses for any specific value of θ, and let the test functions corresponding to θ be $\phi_\theta(\tilde{X}, \tilde{Y})$. Corresponding to $\phi_\theta(\tilde{X}, \tilde{Y})$, let $S \subset R^1$ (real line) be the set of values of θ for which $\phi_\theta(\tilde{X}, \tilde{Y}) = 0$. Then for any θ we have $P_\theta(\theta \in S) = E_\theta(1 - P_\theta(\tilde{X}, \tilde{Y})) \geq 1 - \alpha$. Therefore S is a confidence region of θ with level $1-\alpha$, and if S is always defined as an interval, it gives a nonparametric confidence interval with level $1\text{-}\alpha$.

With a monotone increasing score function we can always construct such a confidence interval as follows:

Let $R_{\theta,i}$ be the rank of $X_i - \theta$, $i = 1, 2, \ldots, n$ in the combined set of values $X_i - \theta$, $i = 1, 2, \ldots, n$ and Y_j, $j = 1, 2, \ldots, m$. Let $c(R)$ be the monotone increasing score function. Then we can determine two constants a and b such that

$$P\left\{a \leq \sum_{i=1}^{n} c(R_{\theta,i}) \leq b\right\} \geq 1 - \alpha$$

Then define

$$\underline{\theta} = \inf\left\{\sum_{i=1}^{n} c(R_{\theta,i}) \leq b\right\}$$

$$\overline{\theta} = \sup\left(\sum_{i=1}^{n} c(R_{\theta,i}) \geq a\right)$$

Since $\sum_{i=1}^{n} c(R_{\theta,i})$ is monotone non-increasing in θ, $\underline{\theta} < \theta < \overline{\theta}$ gives a confidence interval of level $1-\alpha$.

Also from the consideration of the permutation distribution of $T = \sum_{i=1}^{n} X'_i$, we can construct a nonparametric confidence interval of the form

$$\overline{X} - \overline{Y} - D < \overline{\theta} < \overline{X} - \overline{Y} + D$$

When n and m are large, asymptotic results can be applied, and the above interval becomes nearly equivalent to the t-interval derived from the assumption of normality.

Abstract

From its early beginnings in the early 1900s, nonparametric statistics has been an active area that has stimulated elegant statistical theory and beautiful applications. Its development continues at a vigorous pace today. There are many reasons for the success of the nonparametric approach. Nonparametric methods have wide applicability and typically require only modest assumptions concerning the underlying populations from which the data are drawn. Under these mild assumptions, exact hypothesis tests, exact confidence intervals, exact multiple comparison procedures, and exact confidence bands can be obtained. Nonparametric methods have excellent efficiency properties with respect to their parametric competitors and are also robust in the sense that they are relatively insensitive to outlying observations and departures from the model. This article highlights some classical rank-based nonparametric methods in two- and κ-sample location problems. These problems and their generalizations were central to the early development of non-parametric methods and remain extremely useful for data analysis today.

A nonparametric statistical procedure is a statistical procedure, such as (1) a hypothesis test, (2) a confidence interval, (3) a multiple comparison procedure, (4) a confidence band, that has desirable properties that hold under mild assumptions concerning the underlying population from which the data are drawn. Typically, it suffices to assume the underlying population is continuous.

The term 'distribution-free' has a more precise meaning than the term 'nonparametric.' For example, in the context of hypothesis testing, a distribution-free statistic is one whose probability distribution, under the null hypothesis being tested, is independent of the underlying population distribution. In the context of interval estimates, a distribution-free $100(1-\alpha)\%$ confidence interval, say (Δ_L, Δ_U) for an unknown parameter Δ, is a random interval having the property that the probability that Δ is contained in the random interval is $1-\alpha$, independent of the underlying population distribution. There are related concepts for distribution-free multiple comparison procedures (see Section The κ-Sample Problem) and distribution-free confidence bands for distribution functions (see Section 11.5 of Hollander and Wolfe, 1999).

The success of nonparametric statistics over the last 70 years and its continued vigorous development today are due to the wide applicability of the nonparametric approach and the excellent efficiency properties of nonparametric procedures. Some of the main advantages can be briefly summarized as follows:

1. Nonparametric procedures provide exact P-values for tests, exact coverage probabilities for confidence intervals, exact experimentwise error rates for multiple comparison procedures, and exact coverage probabilities for confidence bands. These exact properties do not require an assumption that the underlying population have a specific form, such as a normal population.
2. Nonparametric procedures have excellent efficiency properties with respect to their parametric competitors.
3. Nonparametric procedures are relatively insensitive to outlying observations in the sense that a few wildly big (or small) observations that are far removed from their fellow observations have little influence on the procedure (test, confidence interval, multiple comparison procedure, etc.).

Section The k-sample Problem describes some basic aspects of two- and k-sample location problems. These problems and their generalizations drove the early development of nonparametric statistics, and the procedures developed remain extremely useful for data analysis today. More modern topics in nonparametrics include Bayesian and computationally intensive procedures. Section 1.7 of Hollander and Wolfe (1999) provides a brief history of nonparametric statistics and contains source references to work in other currently active areas including regression problems and survival analysis. Other recent books covering various aspects of nonparametric statistics include Sprent (1993), Gibbons (1997), and Hettmansperger and McKean (1998). Earlier applied books featuring nonparametric methods based on ranks include Noether (1967) and Lehmann (1975). Randles and Wolfe (1979) is an introduction to the theory of nonparametric statistics.

Rank-Based Procedures for Location Alternatives

The primary reasons for using ranks are to obtain exact procedures that enjoy a distribution-free property and to achieve robustness by diminishing the deleterious effects of outlying observations and departures from the model. One might think that the reduction to ranks from original data values would sacrifice too much information, but power and efficiency studies have shown that is not the case. Indeed the nonparametric rank-based procedures are only slightly less efficient than their normal theory competitors when the underlying populations are normal (the home court of normal theory methods), and can be much more efficient when the underlying populations are not normal. We begin our description of rank-based methods with procedures for the two-sample location problem, then consider the k-sample location problem and the

multivariate two-sample location problem. There is an analogous body of nonparametric techniques (which parallels the methods described in Section The k-sample Problem) for one-sample problems, paired-sample problems, randomized blocks, and multivariate one-sample problems. That body of procedures also enjoys excellent efficiency and robustness properties. See Hollander and Wolfe (1999) and Hettmansperger and McKean (1998) for coverage of these methods.

The Two-Sample Location Problem

A basic problem in statistics is the two-sample location problem. Assume that we have a random sample $X_1, \ldots, X_m$ from population 1 having distribution function $F(x) = P(X \le x)$ and an independent random sample $Y_1, \ldots, Y_n$ from population 2 having distribution function $G(x) = P(Y \le x)$. We wish to test the null hypothesis H_0 that the two populations are equivalent, that is,

$$H_0 : F(x) = G(x), \quad \text{for all } x \qquad [1]$$

If we are interested in location alternatives, these can be modeled using the location shift model

$$G(x) = F(x - \Delta), \quad \text{for all } x \qquad [2]$$

where the parameter Δ is commonly called the 'treatment' effect. Model [2] signifies that a randomly selected value Y from population 2 has the same distribution as $X + \Delta$ where X is a randomly selected value from population 1, that is $Y \overset{d}{=} X + \Delta$ where $\overset{d}{=}$ means 'has the same distribution as.' When $\Delta = 0$, H_0 is satisfied. In addition to testing H_0, it is useful to estimate Δ and give a confidence interval for Δ. An excellent way to test H_0, estimate Δ, and give a confidence interval for Δ is to use procedures based on (and derived from) the famous Wilcoxon (1945) two-sample rank sum statistic.

The Wilcoxon two-sample rank sum statistic is

$$W = \sum_{j=1}^{n} R(Y_j) \qquad [3]$$

where $R(Y_j)$ is the rank of Y_j in the joint ranking from least to greatest of the $N = m + nX$ and Y. Significantly large values of W indicate $\Delta > 0$; significantly small values of W indicate $\Delta < 0$. A one-sided upper-tail distribution-free test of H_0:$\Delta = 0$ versus H_1:$\Delta > 0$, at the α level of significance is,

$$\text{reject } H_0 \text{ if } W \ge w_\alpha; \quad \text{otherwise accept } H_0 \qquad [4]$$

where w_α is chosen to make the type-I error probability of the test equal to α and is the upper α^{th} percentile point of the null distribution of W.

Similarly, a one-sided lower-tail distribution-free test of H_0:$\Delta = 0$ versus H_2:$\Delta < 0$, at the $\acute{a}$ level of significance, is

$$\text{reject } H_0 \text{ if } W \le n(m+n+1) - w_\alpha; \quad \text{otherwise accept } H_0 \qquad [5]$$

A two-sided distribution-free test of H_0:$\Delta = 0$ versus H_3:$\Delta \ne 0$, at the α level of significance, is

$$\text{reject } H_0 \text{ if } W \ge w_{\alpha/2} \text{ or if } W \le n(m+n+1) - w_{\alpha/2}; \quad \text{otherwise accept } H_0 \qquad [6]$$

This is the two-sided symmetric test with $\alpha/2$ probability in each tail of the distribution.

The tests based on W are distribution-free under H_0 (eqn [1]) assuming the common value of F and G is a continuous distribution. For then, all $\binom{N}{n}$ possible assignments of the Y-ranks are equally likely, each having probability $1\backslash\binom{N}{n}$ when H_0 is true. Values of w_a can be obtained from Table A.6 of Hollander and Wolfe (1999). Exact p-values can also be obtained using the software StatXact (1999).

The large sample approximation to procedure [4] is

$$\text{reject } H_0 \text{ if } W^* \ge z_\alpha; \quad \text{otherwise accept } H_0 \qquad [7]$$

where

$$W^* = \frac{W - E(W)}{\{\text{var}_0(W)\}^{1/2}} = \frac{W - \{n(m+n+1)/2\}}{\{mn(m+n+1)/12\}^{1/2}} \qquad [8]$$

is the standardized version of W. It can be treated as an approximate $N(0, 1)$ random variable under H_0. In eqn [7], z_α is the upper α percentile point of an $N(0, 1)$ distribution.

If ties are present in the data, assign to tied observations the average of the ranks for which those observations are competing. Then procedure [4] remains applicable but it is now approximate rather than exact. Alternatively, one can use an exact conditional test based on the exact conditional randomization distribution of W, see Hollander and Wolfe (1999: Comment 4.5). When there are ties, the null mean $E_0(W)$ is unchanged but the null variance $\text{var}_0(W)$ is reduced to the right-hand-side of eqn [9]. Thus when applying the large sample approximation in the presence of ties, use average ranks and replace $\text{var}_0(W)$ in eqn [8] by

$$\text{var}_0(W) = \frac{mn}{12}\left(m + n + 1 - \frac{\sum_{j=1}^{g}(t_j - 1)t_j(t_j + 1)}{(m+n)(m+n-1)}\right) \qquad [9]$$

where g denotes the number of tied groups, t_j is the size of tied group j, and an untied observation is considered to be a tied group of size 1.

Thus far in this section we have considered testing H_0:$\Delta = 0$. To test $H_0'' : \Delta = \Delta_0$ where Δ_0 is some specified nonzero number, subtract Δ_0 from each Y to form $Y_1' = Y_1 - \Delta_0, \ldots, Y_n' = Y_n - \Delta_0$. Then compute W as the sum of the ranks of Y' in the joint ranking from least to greatest of the mX's and the nY''s. With W computed in this manner, the procedures described earlier in this section may be directly applied to test H_0''.

There are medical situations for comparing treatments when various restricted randomization designs are employed. In such situations, the test based on W will differ from that described here. See Hollander and Peña (1988) and Mehta et al. (1988) for details.

A point estimator of Δ, derived from the Wilcoxon rank sum statistic, is the Hodges–Lehmann (1963) estimator, namely

$$\hat{\Delta} = \text{median}\left\{Y_j - X_i, i = 1, \ldots, m, j = 1, \ldots, n\right\} \qquad [10]$$

That is, $\hat{\Delta}$ is the median of the $mn(Y - X)$ differences. Roughly speaking $\hat{\Delta}$ is the value $\hat{\Delta}$ that should be subtracted from each Y so that the value of W, when applied to the

aligned samples $X_1, \ldots, X_m, Y_1 - \hat{\Delta}, \ldots, Y_n - \hat{\Delta}$, is equal to $n(m+n+1)/2$. One can think of the method as estimating Δ by the amount $\hat{\Delta}$ the Y's should be shifted so that the sample $X_1, \ldots, X_m$ and the pseudo-sample $Y_1 - \hat{\Delta}, \ldots, Y_n - \hat{\Delta}$ look like two samples from the same distribution as viewed by W.

A symmetric two-sided $100(1-\alpha)\%$ distribution-free confidence interval for Δ, obtained by inverting the test statistic, is

$$\Delta_L = U^{(c_\alpha)}, \quad \Delta_U = U^{(mn+1-c_\alpha)} \qquad [11]$$

where

$$C_\alpha = \frac{n(2m+n+1)}{2} + 1 - w_{\alpha/2} \qquad [12]$$

$w_{\alpha/2}$ is the upper $\alpha/2$ percentile point of the null distribution of W, and $U^{(1)} \leq \cdots \leq U^{(mn)}$ denote the ordered values of the $mn(Y-X)$ differences. For large m and n, the integer C_α may be approximated by

$$C_\alpha \approx \frac{mn}{2} - z_{\alpha/2}\left(\frac{mn(m+n+1}{12}\right)^{1/2} \qquad [13]$$

The value C_α given by eqn [13] will typically not be an integer. To be conservative, when using the large sample approximation to the confidence interval, take C_α to be the largest integer that is less than or equal to the right-hand-side of eqn [13].

Example 1

We illustrate the two-sample Wilcoxon procedures with data from March et al. (1976) (see also Hollander and Wolfe, 1999) who examined differences between healthy and lead-poisoned Canadian geese. One of the measures they considered was plasma glucose (in mg/100 ml plasma). The data for eight healthy geese and seven lead-poisoned geese are given in **Table 1**. From **Table 1**, we find $W = 68$. Referring $W = 68$ to Table A.6 of Hollander and Wolfe (1999) with $n = 7$ and $m = 8$, we find $P_0(W \geq 68) = 0.095$. (In Table A.6, $n \leq m$, therefore designate the values corresponding to the smaller sample as Y.) That is, the probability, under the null hypothesis, of getting a value as larger or larger than 68, is 0.095. This is the p-value for the one-sided test of $\Delta = 0$ versus $\Delta > 0$. (StatXact software gives the p-value 0.094 6). Thus one would reject $\Delta = 0$ in favor of $\Delta > 0$ for all type-I error probabilities $\alpha \geq 0.095$ and accept $\Delta = 0$ for all type-I error probabilities $\alpha < 0.095$. Thus there is borderline evidence that the lead-poisoned geese have higher plasma glucose values.

Table 1 Plasma glucose values for healthy and lead-poisoned Canadian geese (ranks in parentheses)

Healthy geese	*Lead-poisoned geese*
297(8)	293(7)
340(12)	291(6)
325(10)	289(4)
227(1)	430(14)
277(3)	510(15)
337(11)	353(13)
250(2)	318(9)
290(5)	

Source: March, G.L., John, T.M., McKeown, B.A., Sileo, L., George, J.C. 1976. The effects of lead poisoning on various plasma constituents in the Canada goose. Journal of Wildlife Diseases 12, 14–19.

To compute the Hodges–Lehmann estimate $\hat{\Delta}$, we first obtain the ordered $Y - X$ differences $U^{(1)} \leq \cdots \leq U^{(56)}$. The ordered differences are: −51, −49, −48, −47, −46, −44, −36, −34, −32, −22, −19, −8, −7, −6, −4, −1, 1, 3, 12, 13, 14, 16, 16, 21, 28, 28, 39, 41, 41, 43, 56, 62, 63, 64, 66, 68, 76, 90, 91, 93, 103, 105, 126, 133, 140, 153, 170, 173, 180, 185, 203, 213, 220, 233, 260, 283. Then $\hat{\Delta}$ is found to be 41, the average of $U^{(28)}$ and $U^{(29)}$. To obtain a 96% confidence interval, set $\alpha/2 = 0.02$ and from Table A.6 of Hollander and Wolfe (1999) obtain $w_{0.02} = 74$. Then from eqn [12], $C_{0.04} = 11$, and from eqn [11] we obtain $\Delta_L = U^{(11)} = -19$, $\Delta_U = U^{(46)} = 153$.

The *k*-Sample Problem

The two-sample problem of Section The Two-Sample Location Problem is readily extended to $k \geq 2$ samples, one sample from each of k populations. The basic null hypothesis is that the k samples can be viewed as a single combined sample from a common population. Typically we are interested in alternatives that specify that the locations (medians, means) of the k populations are not equal. More formally, let $X_{ij}, X_{2j}, \ldots, X_{n_j j}$ denote the random sample of n_j observations from the jth population, which is assumed to have an unknown continuous distribution F_j, $j = 1, \ldots, k$ where $F_j(x) = P(X_{ij} \leq x)$ for $i = 1, \ldots, n_j$. We also assume that all $N = \sum_{j=1}^{k} n_j$ random variables are mutually independent. The null hypothesis of equivalent populations is

$$H_0 : F_1(x) = F_2(x) = \ldots = F_k(x), \quad \text{for all } x \qquad [14]$$

To study location alternatives it is natural to introduce the location shift model

$$F_j(x) = F(x - \tau_j), \quad j = 1, \ldots, k \qquad [15]$$

where F is an unknown continuous distribution function and τ_j is the unknown treatment effect corresponding to the jth population. In submodel [15], the null hypothesis H_0 of eqn [14] becomes

$$H_0 : \tau_1 = \tau_2 = \ldots = \tau_k \qquad [16]$$

An excellent way to test H_0 is to use the Kruskal–Wallis test (see Kruskal, 1952; Kruskal and Wallis, 1952). Let τ_{ij} denote the rank of X_{ij} in the joint ranking of all N observations from the k samples. Furthermore, let

$$R_j = \sum_{i=1}^{n_j} r_{ij}, \quad R.j = R_j/n_j, \quad j = 1, \ldots, k \qquad [17]$$

denote, respectively, the sum and average of the ranks received by the jth sample. The Kruskal–Wallis statistic is

$$H = \frac{12}{N(N+1)} \sum_{j=1}^{k} n_j \left(R.j - \frac{N+1}{2}\right)^2$$
$$= \left(\frac{12}{N(N+1)} \sum_{j=1}^{k} \frac{R_j^2}{n_j}\right) - 3(N+1) \qquad [18]$$

Significantly large values of H indicate the τ's are not all equal to a common value. A distribution-free test at the α level of significance, of H_0 in eqn [16], against the alternative that the τ's are not all equal, is

$$\text{reject } H_0 \text{ if } H \geq h_\alpha; \quad \text{otherwise accept } H_0 \qquad [19]$$

where h_α is chosen to make the type-I error probability of the test equal to α and is the upper α^{th} percentile point of the null distribution of H. (For $k = 2$, this test reduces to the two-sided Wilcoxon test of eqn [6]).

The test based on H is distribution-free under H_0 in eqn [14] assuming the common distribution of F is continuous. For then all $N!/(\prod_{j=1}^{k} n_j!)$ possible assignments of n_1 ranks to the sample 1 observations, n_2 ranks to the sample 2 observations, $\ldots n_k$ ranks to the sample k (Hollander and Wolfe, 1999). StatXact performs the exact test as well as the large sample approximation next described.

The large sample approximation to procedure eqn [19] is

$$\text{reject } H_0 \text{ if } H \geq \chi^2_{k-1,\alpha}; \quad \text{otherwise accept } H_0 \qquad [20]$$

where $\chi^2_{k-1,\alpha}$ is the upper αth percentile point of a chi-squared distribution with $k-1$ degrees of freedom.

For a ties correction to the large sample approximation, compute H using average ranks. That is, assign each of the observations in a tied group the average of the ranks those observations would receive if they were not tied. Then refer to H' to a chi-squared distribution with $k-1$ degrees of freedom where

$$H' = H \Bigg/ \left\{ 1 - \left(\sum_{j=1}^{g} \left(t_j^3 - t_j \right) / \left(N^3 - N \right) \right) \right\} \qquad [21]$$

In eqn [21], g denotes the number of tied groups and t_j is the size of tied group j (and an untied observation is considered to be a tied group of size 1). The ties correction of eqn [21] does not yield an exact α level test. To obtain an exact α-level test in the presence of ties, see Hollander and Wolfe (1999: Comment 6.8).

If the hypothesis H_0 in eqn [16] of equivalent treatments is rejected, it is natural to investigate which particular pairs of treatments differ from one another. This is the aim of multiple comparisons. There are various multiple comparison procedures available (cf Miller, 1981; Hettmansperger and McKean, 1998; Hochberg and Tamhane, 1987; Hollander and Wolfe, 1999). Here we will describe and illustrate the multiple comparison procedure proposed independently by Dwass (1960) and Steel (1960) for the equal sample size case and generalized by Critchlow and Fligner (1991) to allow unequal sample sizes. The procedure is based on $\binom{k}{2}$ separate pairwise rankings, corresponding to ranking jointly each pair of samples.

For each pair of treatments (u, v), let W_{uv} denote the Wilcoxon rank sum of the ranks attained by the n_v observations in sample v in the joint ranking of the n_u observations from sample u and the n_v observations from sample v.

Let

$$W^*_{uv} = \sqrt{2}\left(\frac{W_{uv} - E_0(W_{uv})}{\{\text{var}_0(W_{uv})\}^{1/2}} \right)$$
$$= \left(W_{uv} - \frac{n_v(n_u + n_v + 1)}{2} \right) \Bigg/ \left(\frac{n_u n_v (n_u + n_v + 1)}{24} \right)^{1/2},$$
$$1 \leq u < v \leq k \qquad [22]$$

A distribution-free two-sided all treatments multiple comparison procedure, at an experimentwise error rate of α, is

$$\text{decide } \tau_u \neq \tau_v \text{ if } \left| W^*_{uv} \right| \geq w^*_\alpha; \quad \text{otherwise decide } \tau_u = \tau_v \qquad [23]$$

The constant w^*_α is chosen to make the experimentwise error rate equal to α, that is, w^*_α is chosen so that

$$P_0\left(\left| W^*_{uv} \right| < w^*_\alpha,\ u = 1, \ldots, k-1;\ v = u+1, \ldots, k \right) = 1 - \alpha \qquad [24]$$

where the probability $P_0(\cdot)$ is computed under H_0. Selected values of w^*_α can be found in Table A.16 of Hollander and Wolfe (1999). Also see Steel (1960, 1961) and Critchlow and Fligner (1991). A large sample approximation to procedure [23] is

$$\text{decide } \tau_u \neq \tau_v \text{ if } \left| W^*_{uv} \right| \geq q_\alpha; \quad \text{otherwise decide } \tau_u = \tau_v, \qquad [25]$$

where q_α is the upper αth percentile point of the distribution of range of k $N(0, 1)$ random variables. Values of q_α can be found in Table A.17 of Hollander and Wolfe (1999). For the justification of the approximation, see, for example, Hollander and Wolfe (1999: pp. 246–247) and Hochberg and Tamhane (1987). There are also various procedures available to provide simultaneous confidence intervals for contrasts (cf Hollander and Wolfe (1999: Section 6.9) and Hettmansperger and McKean (1998: Section 4.3). Miller (1981) and Hochberg and Tamhane (1987) are books that specialize in multiple comparisons.

Example 2

We illustrate the k-sample procedures of this section with data from (Zelazo et al., 1972) (see also Brown and Hollander, 1977). The study concerned infants who were randomized to one of four treatments to determine if stimulation of the walking and placing reflexes in the newborn accelerates the time at which infants learn to walk by themselves. The subjects of **Table 2** were about 1-week-old male infants from middle-class and upper-middle-class families. Each infant was

Table 2 Ages (in months) of infants for walking alone (ranks in parentheses)

Active exercise	*Passive exercise*	*No exercise*	*8-week*
9.00(1.5)	11.00(10)	11.50(12.5)	13.25(20.5)
9.50(3.5)	10.00(7)	12.00(16.5)	11.50(12.5)
9.75(5)	10.00(7)	9.00(1.5)	12.00(16.5)
10.00(7)	11.75(15)	11.50(12.5)	13.50(22)
13.00(18.5)	10.50(9)	13.25(20.5)	11.50(12.5)
9.50(3.5)	15.00(23)	13.00(18.5)	
$R_1 = 39$	$R_2 = 71$	$R_3 = 82$	$R_4 = 84$

Source: Zelazo, P.R., Zelazo, N.A., Kolb, S., 1972. 'Walking' in the newborn. Science 176, 314–315.

randomly assigned to one of four groups: an experimental group (active exercise) and three control groups (passive exercise, no exercise, eight-week control). We apply the Kruskal–Wallis test to test if there are significant differences among the four groups. The reader will note from the rankings in **Table 2** that there are five tied groups of size 2, one tied group of size 3, and one tied group of size 4. Applying the large sample approximation with the correction for ties given by eqn [21], we find $H' = 6.88$. This agrees with the calculation obtained using StatXact, namely $H' = 6.88$ with an approximate p-value of 0.075 8 obtained by referring $H' = 6.88$ to a chi-squared distribution with three degrees of freedom. Thus there is evidence that the treatments are not equivalent. We now turn to multiple comparisons to see which treatments differ and which yield the earlier times to walking alone.

We will apply the approximate multiple comparison procedure given by eqn [25]. Performing the six two-sample rankings using the data of **Table 2**, we find from eqn [22], $W^*_{12} = 2.717$, $W^*_{13} = 2.038$, $W^*_{14} = 3.098$, $W^*_{23} = 1.132$, $W^*_{24} = 2.066$, and $W^*_{34} = 1.033$. From the distribution of the range of 4 $N(0, 1)$ random variables, we find $q_{0.10} = 3.240$ and $q_{0.20} = 2.784$. Thus at an approximate experimentwise error rate of 0.10, procedure [25] makes no significant decisions but at an experimentwise error rate of 0.20, we decide, since $|W^*{}_{14}| = 3.098 > 2.784$, that $\tau_1 \neq \tau_4$ and there is evidence that active exercise leads to earlier walking than is obtained by the 8-week control. We note that the conservative nature of this experimentwise error rate approach to multiple comparisons (as well as the two-sided procedure used here) makes it difficult to find significant differences at a low experimentwise error rate. If, however, one performs individual one-sided two-sample Wilcoxon rank sum tests of the form given by procedure [4], with sample sizes 6 and 5, as is appropriate for the (1, 4), (2, 4), and (3, 4) comparisons, the $\alpha = 0.063$ critical value for the upper-tail procedure [4] is 39 (see Table A.6, Hollander and Wolfe, 1999) and since W14 = 42, W24 = 38, and $W_{34} = 34$, we find that active exercise leads to earlier walking times than the 8-week control. Similarly, for the individual one-sided two-sample tests with sample sizes 6 and 6, as is appropriate for the (1, 2), (1, 3), and (2, 3) comparisons, the $\alpha = 0.066$ critical value for the upper-tail procedure (4) is 49 (see Table A.6, Hollander and Wolfe, 1999), and since $W_{12} = 51$, $W_{13} = 48$, and $W_{23} = 44$, we are able to judge active exercise as leading to earlier walking times than passive exercise.

The Multivariate Two-Sample Location Problem

The Wilcoxon statistic of Section The Two-Sample Location Problem can be generalized to the multivariate case (cf Puri and Sen, 1971: Chapter 5). Let

$$X^j_\alpha = \left(X^{(j)}_{1\alpha}, \ldots, X^{(j)}_{p\alpha}\right)', \quad \alpha = 1, \ldots, n_j, \quad j = 1, 2 \qquad [26]$$

be independent p-dimensional random vectors with X^j_α having distribution function $F_j(x)$. The hypothesis of eqn [1] is generalized to

$$H_0 : F_1(x) = F_2(x) \quad \text{for all } \boldsymbol{x} \qquad [27]$$

As with the procedures in Sections The Two-Sample Location Problem and The k-sample Problem, we will define a test intended to detect location differences of the form

$$F_j(\boldsymbol{x}) = F(\boldsymbol{x} + \boldsymbol{\delta}_j), \quad j = 1, 2 \qquad [28]$$

where for model [28], H_0 can be written

$$H_0 : \boldsymbol{\delta}_1 = \boldsymbol{\delta}_2 = \mathbf{0} \qquad [29]$$

that is, the random vectors can be viewed as coming from a common p-variate population.

To test H_0 versus the location alternatives $\boldsymbol{\delta}_1 \neq \boldsymbol{\delta}_2$, let W_i be the sum of the second sample's component i ranks in the joint ranking from least to greatest of the $N = n_1 + n_2$ values in the pth component of the first and second samples. We let $R_{i1}, \ldots, R_{in}$ denote the ranks obtained by the first sample and $R_{i,n_1+1}, \ldots, R_{i,n_1+n_2}$ denote the ranks obtained by the second sample in this joint ranking. To compute this multivariate two-sample Wilcoxon-type test, we thus need to perform p two-sample rankings, each of size $N = n_1 + n_2$. Let

$$V_i = W_i - n_2(N+1)/2, \quad i = 1, \ldots, p \qquad [30]$$

and let $\boldsymbol{V} = (V_1, V_2, \ldots, V_p)'$. The test statistic is

$$V^* = \mathbf{V}'\boldsymbol{A}^{-1}\mathbf{V} \qquad [31]$$

where the $p \times p$ matrix $\boldsymbol{A}$ has elements

$$a_{ii} = n_1 n_2 (N+1)/12$$
$$a_{ij} = [n_1 n_2/\{(N-1)N\}] \cdot \left[\sum_{s=1}^{N} R_{is}R_{js} - \left\{N(N+1)^2/4\right\}\right] \qquad [32]$$

The matrix $N^{-3}\mathbf{A}$ is a consistent estimator of the asymptotic covariance matrix of $N^{-(3/2)}\boldsymbol{V}$.

An asymptotically distribution-free test of H_0 defined by eqn [27] against the location alternatives $\boldsymbol{\delta}_1 \neq \boldsymbol{\delta}_2$, at the approximate α level, rejects H_0 if $V^* > \chi^2_{p,\alpha}$. This test is not distribution-free for finite samples, but a conditionally distribution-free test based on V^* can be obtained using a permutation principle (Section 5.3, Puri and Sen, 1971).

For simplicity we have chosen to describe (and illustrate in Example 3 below) the multivariate two-sample Wilcoxon test. For the k-sample multivariate Wilcoxon test, see Puri and Sen (1971: Chapter 5). For point estimation of $(\boldsymbol{\delta}_1, \boldsymbol{\delta}_2)$ see Section 6.3 of Puri and Sen (1971) and for Bonferoni confidence bounds for $(\boldsymbol{\delta}_1, \boldsymbol{\delta}_2)$, see Puri and Sen (1971: pp. 258–259).

Example 3

The taste aversion data in **Table 3** are from J.C. Smith and P. Smith (personal communication, 1999). Taste aversion learning is a situation in which an animal (or human) drinks a taste solution and then is subjected to some uncomfortable experience (e.g., radiation exposure, injection of some toxic drug such as lithium chloride, exposure to a high intensity magnet, etc.). After the 'pairing' of the taste and the drug, the subject is subsequently tested with the taste solution to see if an aversion has occurred. There has been much interest in how and where this association of taste and drug is made in the brain. It involves: (1) Where is the taste sensation mediated in the brain? (2) Where is the drug sensation mediated in the

Table 3 Total water intake (component ranks in parentheses)

	Day 1	*Day 2*	*Day 3*	*Day 4*	*Day 5*	*Day 6*

	$W_1 = 47$	$W_2 = 47.5$	$W_3 = 48$	$W_4 = 46$	$W_5 = 50$	$W_6 = 51$

Source: J.C. Smith and P. Smith (private communication, 1999).

brain? (3) Where is the association of the taste and drug mediated?

Taste is 'sensed' by taste nerves in the oral cavity and makes the first synapse in the nucleus of the solitary tract and the second synapse in the parabrachial nucleus (PBN). R. Norgren believes that the association (point (3) above) is made in the PBN. He has shown that when he destroys the PBN, a rat is unable to learn a conditioned taste aversion. In contrast, the rat can learn an aversion that does not involve taste, but does involve texture, temperature, etc. J.C. Smith and P. Smith can take a rat that normally prefers cold water over warm water, give it a pairing of cold water with lithium chloride and turn it into a warm water 'preferrer.' Norgren sent Smith and Smith some PBN-operated rats (along with some sham-operated controls) for testing with the warm/cold water procedure. Norgren predicted the PBN rat could learn the warm/cold discrimination since there is no reason to think this involves taste. The problem with making lesions in the brain is that most of the brain parts do more than one thing. Before Smith and Smith tested rats for Norgren, they felt it was a good idea to see if the PBN rats eat laboratory food and drink water like normal rats. The data in **Table 3**, with $n_1 = 7$ PBN-lesion rats and $n_2 = 6$ control rats, come from those observations. They represent a group of rats with PBN lesions and a control group that received surgery but the PBN was spared. Smith and Smith measured water intake over 6 days. They suspected a priori that there might be decrement in water drinking for the PBN rats. The analysis based on the two-sample multivariate Wilcoxon test leads to the conclusion that there are no significant differences between the two groups.

We used an S-plus program to calculate $V^*(31)$ and found $V^* = 5.368$. Referring $V^* = 5.368$ to a chi-squared distribution with four degrees of freedom yields a p-value of 0.498. Thus there is no evidence of differences in total water intake between the PBN and control groups. We note, however, that the test based on V^* is two-sided. Since Smith and Smith suspected a priori that the PBN rats might drink less, we should also check the one-sided p-values associated with the one-sided two-sample Wilcoxon test [4] to see if there is evidence that the PBN rats did less drinking. The one-sided p-values corresponding to $W_1 = 47$, $W_2 = 47.5$, $W_3 = 48$, $W_4 = 46$, $W_5 = 50$, and $W_6 = 51$ are (from Table A.6, Hollander and Wolfe, 1999), respectively 0.267, 0.267, 0.223, 0.314, 0.147, 0.117. Thus, again, we do not find significant differences between the two groups. In other words the individual tests are consistent with the overall test based on V^*. The latter, of course, accounts of the dependencies between days.

Efficiencies of Location Procedures

The location procedures of Sections The Two-Sample Location Problem, The k-Sample Problem, and The Multivariate Two-Sample Location Problem have desirable efficiency properties with respect to their parametric competitors derived under the distributional assumption of normality. For translation alternatives, the Pitman asymptotic relative efficiency (Puri and Sen (1971: Section 3.8.1)) of the test based on W with respect to the normal theory two-sample t-test is

$$E(W,t) = 12\sigma_F^2\left(\int f^2(x)\mathrm{d}x\right)^2 \qquad [33]$$

where σ_F^2 is the variance of the population with distribution F and f is the probability density corresponding to F. Expression [33] is also the asymptotic relative efficiency of the estimator $\hat{\Delta}$ in eqn [10] with respect to $\overline{\Delta} = \overline{Y} - \overline{X}$ (Hodges and Lehmann, 1963); the asymptotic relative efficiency of the confidence interval given by eqn [11] relative to the normal theory confidence interval centered at $\overline{\Delta}$ (Lehmann, 1963); the asymptotic relative efficiency of the Kruskal–Wallis test relative to the normal theory one-way layout $\mathscr{F}$-test (Andrews, 1954); the asymptotic relative efficiency of the multiple comparison procedure [23] with respect to the corresponding normal theory procedure based on sample means (Sherman, 1965). Hodges and Lehmann (1956) showed that for all populations $E(W, t)$ is at least 0.864. Values of this efficiency expression for various distributions are given in **Table 4**. The Pitman asymptotic relative efficiency of the test based on V^* in eqn [31] with respect to a likelihood ratio criterion test is quite complicated and depends on the univariate marginal distributions and bivariate marginal distributions of F. It is given by Puri and Sen (1971: p. 212).

Table 4 Values of $E(W, t)$ for various distributions

F	*Normal*	*Uniform*	*Logistic*	*Double-exponential*	*Cauchy*	*Exponential*
$E(W, t)$:	0.955	1.000	1.097	1.500	∞	3.00

Conclusion

We have highlighted some rank-based procedures in two- and *k*-sample location problems. These procedures and their generalizations played a key role in the early development of nonparametric statistics. They remain attractive to data analysts today because they enjoy excellent efficiency properties, they are relatively insensitive to outliers, and they are valid under very mild assumptions concerning the underlying populations from which the data are obtained. The subject of nonparametric statistics continues to be vigorously studied. Areas of interest at the time of this writing include Bayesian and computer intensive methods (*See* Nonparametric Statistics: Advanced Computational Methods), regression, and survival analysis. Recent books on nonparametric statistics that would be useful to the interested reader include Sprent (1993), Gibbons (1997), Hettmansperger and McKean (1998), and Hollander and Wolfe (1999).

Abstract

In 1952, Chandler defined the so-called record times and record values. Records arise naturally in many fields of studies such as climatology, sports, medicine, traffic, and so on. The classical record schemes are based on sequences of independent identically distributed random variables. In the first part of the article, different types of the classical records are discussed. In the second part of the article, some modern generalizations of the classical record schemes are given. The so-called F^{α}-scheme, linear draft record model, δ-exceedance record scheme, and the models of records with restrictions and confirmations are presented here.

In 1952, Chandler defined the so-called record times and record values and laid the groundwork for a mathematical theory of records. For six decades, beginning with his pioneering work, there appeared about 500 papers and some monographs devoted to different aspects of the theory of records. This theory relies largely on the theory of order statistics and is especially closely connected to extreme order statistics. Records are very popular because they arise naturally in many fields of studies such as climatology, sports, medicine, traffic, industry, and so on. The records as such are memorials of their time. The annals of records reflect the progress in science and technology and enable us to study the evaluation of mankind on the basic of record achievements in various areas of its activity. A large number of record data saved for a long time inspirited the appearance of different mathematical models reflecting the corresponding record processes and forecasting the future record results.

Definitions of Records

Let X_1, X_2, … be a sequence of random variables and $X_{1,n} \le X_{2,n} \le \ldots \le X_{n,n}$, $n = 1,2,\ldots$, be the corresponding order statistics. For any $n = 1,2,\ldots$ denote also $M(n) = X_{n,n} = \max\{X_1, X_2,\ldots,X_n\}$ and $m(n) = X_{1,n} = \min\{X_1,X_2,\ldots,X_n\}$. Now one can define the classical upper record times $L(n)$ and upper record values $X(n)$ as follows: $L(1) = 1$, $X(1) = X_1$ and then,

$$L(n+1) = \min\left\{j : X_j > X(n)\right\}, \quad X(n+1) = X_{L(n+1)}, \quad n = 1,2,\ldots \tag{1}$$

One can use the following alternative definitions:

$$L(1) = 1, \quad L(n+1) = \min\left\{j : X_j > M(L(n))\right\}, \quad n = 1,2\ldots, \quad \text{and} \quad X(n) = M(L(n)), \quad n = 1,2,\ldots \tag{2}$$

If we replace the sign $>$ and $M(L(n))$ in [2] by $<$ and $m(L(n))$, respectively, we obtain the definitions of the lower record times and the lower record values. Indeed, the theories of upper and lower records coincide practically in all their details, since the lower records for the sequence $-X_1,-X_2,\ldots$ correspond to the upper records for the sequence $X_1,X_2,\ldots$. Using the sign $\ge$ in [1] instead of $>$ we introduce the so-called weak upper records, when any repetition of the previous record value is also considered as a new record. Analogically, the sign $\le$ in [1] gives the opportunity to define the weak lower record times and the weak lower record values. Note that the theory of weak records has practical meaning only for sequences of the initial X's, which have discrete distributions.

The so-called *k*th records are a natural extension of records. The *k*th record times $L(n,k)$ and the *k*th record values $X(n,k)$ for any $k = 1,2,\ldots$ are defined as follows:

$$L(1,k) = k, \quad L(n+1,k) = \min\left\{j > L(n,k) : X_j > X_{j-k,j-1}\right\}, \quad n = 1,2,\ldots, \tag{3}$$

and

$$X(n,k) = X_{L(n,k)-k+1,L(n,k)}, \quad n = 1,2,\ldots \tag{4}$$

To be precise, [3] and [4] define the *k*th upper record times and the *k*th upper record values, respectively. One can also introduce the *k*th lower record times and the *k*th lower record values changing the event $X_j > X_{j-k,j-1}$ in [3] by $X_j < X_{k,j-1}$ and replacing $X_{L(n,k)-k+1,L(n,k)}$ in [4] by $X_{k,L(n)}$. If $k = 1$, then definitions of *k*th record values $X(n,k)$ and *k*th record times $L(n,k)$ coincide with the definitions of $X(n)$ and $L(n)$ given in [1].

We will use $N(n)$ to denote the number of records among random variables $X_1,X_2,\ldots,X_n$, $n = 1,2,\ldots$, and $N(n,k)$ will denote the number of *k*th records in a sequence $X_1,X_2,\ldots,X_n$ respectively.

Sequential Ranks and Record Indicators

The essential role in the theory of records is played by the sequential ranks $R(n)$, the record indicators ξ_j, $j = 1,2,\ldots$, and the indicators of the *k*th records $\xi_j(k)$, $j = 1,2,\ldots$, $k = 1,2,\ldots$. The sequential rank $R(n)$ denotes the rank of X_n among $X_1,X_2,\ldots,X_n$, i.e.,

$$X_n = X_{R(n),n}, \quad n = 1,2,\ldots$$

The record indicator ξ_j is defined as follows: $\xi_j = 1$ if X_j is a record value and $\xi_j = 0$ otherwise. Analogically, the indicator $\xi_j(k)$ can be defined for any $k = 1,2,\ldots$ and $j \ge k$.

$\xi_j(k) = 1$, if X_j is the kth record value and $\xi_j(k) = 0$ otherwise. There are some useful relations between record indicators and sequential ranks. We will formulate some simple equalities for indicators of the upper records. Indeed, analogical results are also valid for the lower records. Note, that

$$\{\xi_j = 1\} = \{R(j) = j\} = \{X_j = M(j)\} = \{X_j = X_{j,j}\} = \{X_j \text{ is a record value}\}$$

and for any $k = 1,2,\ldots$ and $j \geq k$

$$\{\xi_j(k) = 1\} = \{R(j) \geq j-k+1\} = \{X_{j-k+1,j} \geq X_{j-k,j-1}\} = \{X_j > X_{j-k,j-1}\} = \{X_j \text{ is a } k\text{th record}\}$$

The record indicators allow us to give convenient relations for the numbers of records $N(n)$ and $N(n,k)$:

$$\{N(n) = m\} = \{\xi_1 + \ldots + \xi_n = m\}, \quad n = 1,2,\ldots, \quad m = 1,2,\ldots,n \qquad [5]$$

$$\{N(n,k) = m\} = \{\xi_k(k) + \ldots + \xi_n(k) = m\}, \quad n = k, k+1, \ldots, \quad m = 1,2,\ldots,n-k+1 \qquad [6]$$

The classical theory of records is connected with the situation, when the initial sequence of random variables $X_1,X_2,\ldots$ is a sequence of independent random variables with a common continuous distribution function (d.f.). In this case, sequential ranks and record indicators have a number of useful and rather convenient properties.

Theorem 1

For independent identically distributed random variables $X_1,X_2,\ldots$ with a continuous distribution function F the sequential ranks $R(1)$, $R(2),\ldots$ are independent and $P\{R(n) = m\} = 1/n$, $m = 1,2,\ldots,n$, $n = 1,2,\ldots$.

Theorem 2

Under conditions of theorem 1, for any fixed $k = 1,2,\ldots$, indicators $\xi_k(k)$, $\xi_{k+1}(k),\ldots$ are independent and $P\{\xi_j(k) = 1\} = k/j$, $j = k, k+1,\ldots$.

As a partial case of theorem 2, it follows that, under conditions of theorem 1, record indicators $\xi_1,\xi_2,\ldots$ are independent and

$$P\{\xi_j = 1\} = 1 - P\{\xi_j = 0\} = 1/j, \quad j = 1,2,\ldots$$

These results together with equalities [5] and [6] allow us to find that the distributions of $N(n)$ and $N(n,k)$ are expressed as distributions of sums of independent random variables. One can see also that under conditions of theorem 1 there are some convenient relations for the kth record times $L(n,k)$ and, in particular, for the record times $L(n)$:

$$P\{L(n,k) > m\} = P\{N(m,k) < n\} = P\{\xi_k(k) + \xi_{k+1}(k) + \ldots + \xi_m(k) < n\} \qquad [7]$$

and

$$P\{L(n) > m\} = P\{N(m) < n\} = P\{\xi_1 + \xi_2 + \ldots + \xi_m < n\} \qquad [8]$$

It follows from relations [7] and [8] that if $X_1,X_2,\ldots$ is a sequence of independent identically distributed (i.i.d.) random variables with any continuous d.f. F, then distributions of record times and numbers of records do not depend on F.

One more important situation in the classical record theory is connected with sequences of i.i.d. random variables having a discrete distribution. Without loss of generality, we can suppose that X's take nonnegative integer values. For discrete distributions, we introduce another type of record indicators. Let $\eta_n = 1$, if n is a record value in the sequence $X_1,X_2,\ldots$, that is there exists such $m = 1,2,\ldots$ that $X(m) = n$, and $\eta_n = 0$ otherwise (compare with indicators ξ_n!). Analogously, for any $k = 1,2,\ldots$ we can introduce indicators $\eta_n(k)$ for *kth* record values: $\eta_n(k) = 1$, if n is a kth record value in the sequence $X_1,X_2,\ldots$, and $\eta_n(k) = 0$ otherwise. The following results are valid for such type of indicators.

Theorem 3

Let $X,X_1,X_2,\ldots$ be a sequence of independent identically distributed random variables taking values $0,1,2,\ldots$ with probabilities $p_n = P\{X = n\} > 0$, $n = 0,1,2,\ldots$. Then for any fixed $k = 1,2,\ldots$ indicators $\eta_n(k)$, $n = 0,1,2,\ldots$, are independent and

$$P\{\eta_n(k) = 1\} = 1 - P\{\eta_n(k) = 0\} = (p_n/P\{X^3 \geq n\})^k, \quad n = 0,1,2,\ldots$$

Indeed, under $k = 1$, as a partial case of this theorem, one gets that record indicators $\eta_0,\eta_1,\eta_2,\ldots$ are independent and $P\{\eta_n = 1\} = 1-P\{\eta_n = 0\} = p_n/P\{X \geq n\}$, $n = 0,1,2,\ldots$.

It is easy to see that under conditions of theorem 3 we can express distributions of kth record values for discrete random variables via distributions of sums of independent indicators:

$$P\{X(n,k) > m\} = P\{\eta_0(k) + \ldots + \eta_m(k) < n\}, \quad m = 0,1,2,\ldots, \quad n = 1,2,\ldots, \qquad [9]$$

and, in particular, under $k = 1$ one has equality

$$P\{X(n) > m\} = P\{\eta_0 + \ldots + \eta_m < n\}, \quad m = 0,1,2,\ldots, \quad n = 1,2,\ldots \qquad [10]$$

As an example, we can consider the case, when X's have the geometric distribution with some parameter $0 < p < 1$, that is

$$P\{X_j = n\} = (1-p)p^n, \quad n = 0,1,2,\ldots, \quad \text{for} \quad j = 1,2,\ldots$$

In this situation

$$P\{\eta_n(k) = 1\} = (1-p)^k \text{ and}$$
$$P\{\eta_n(k) = 0\} = 1-(1-p)^k, \quad \text{for any } n = 0,1,2,\ldots$$

It means that the sum $\eta_0(k) + \ldots + \eta_m(k)$ has the binomial $B(m+1,q)$ distribution with a parameter $q = (1-p)^k$. Hence

$$P\{X(n,k) > m\} = \sum_{j=0}^{n-1}((m+1)!/j!(m+1-j)!)q^j(1-q)^{m+1-j}, \quad \text{if } 1 \leq n \leq m+1$$

and

$$P\{X(n,k) > m\} = 1, \quad \text{if } n > m+1$$

It was mentioned above that for discrete distributions, it is useful to introduce weak records together with classical (strong) record values. Weak records may arise, for example, in some sport competitions where any athlete who repeats the record achievement is also declared as a record holder. If we consider X's having a common discrete distribution, it is useful to introduce one more type of record statistics. Let the conditions of theorem 3 be valid. We define random variables $\mu_0,\mu_1,\mu_2,\ldots$, where μ_n denotes the number of those weak records in the sequence $X_1,X_2,\ldots$ that are equal to n. The following result is valid.

Theorem 4

Let $X,X_1,X_2,\ldots$ be a sequence of independent identically distributed random variables taking values $0,1,2,\ldots$ with probabilities $p_n = P\{X = n\} > 0$, $n = 0,1,2,\ldots$. Then for any fixed $k = 1,2,\ldots$, random variables $\mu_0,\mu_1,\mu_2,\ldots$ are independent and

$$P\{\mu_n = m\} = (1 - r(n))\,(r(n))^m,$$
$$n = 0,1,2,\ldots,\quad m = 0,1,2,\ldots$$

where

$$r(n) = p_n/P\{X \geq n\}$$

Let $X_\omega(1),X_\omega(2),\ldots$ denote the weak (upper) record values in the sequence $X_1,X_2,\ldots$. Then for any $n = 1,2,\ldots$ and $m = 0,1,2,\ldots$ the following relation is valid:

$$P\{X_\omega(n) > m\} = P\{\mu_0 + \mu_1 + \ldots + \mu_m < n\} \qquad [11]$$

Thus we see that there are some convenient representations of record values, record times, numbers of records ([5–11] among them), which allow us to impress these record statistics in terms of sums of independent random variables.

Distributions of Record Times

Let us consider the classical case, when $X_1,X_2,\ldots$ are independent and have a continuous d.f. F. Using the independence of the corresponding record indicators $\xi_1,\xi_2,\ldots$ one gets for any $n = 1,2,\ldots$ and $1 < j(1) < j(2) < \ldots < j(n)$ that

$$\begin{aligned}
&P\Big\{L(1) = 1, L(2) = j(2), \ldots, L(n) = j(n)\Big\}\\
&= P\Big\{\xi_1 = 1, \xi_2 = 0, \ldots, \xi_{j(2)-1} = 0, \xi_{j(2)} = 1, \xi_{j(2)+1} = 0, \ldots,\\
&\qquad \xi_{j(3)-1} = 0, \xi_{j(3)} = 1, \ldots, \xi_{j(n)-1} = 0, \xi_{j(n)} = 1\Big\}\\
&= P\Big\{\xi_1 = 1\Big\}P\Big\{\xi_2 = 0\Big\}\ldots P\Big\{\xi_{j(2)-1} = 0\Big\}P\Big\{\xi_{j(2)} = 1\Big\}\\
&\quad \times P\Big\{\xi_{j(2)+1} = 0\Big\}\ldots P\Big\{\xi_{j(3)-1} = 0\Big\}P\Big\{\xi_{j(3)} = 1\Big\}\ldots\\
&\quad \times P\Big\{\xi_{j(n)-1} = 0\Big\}P\Big\{\xi_{j(n)} = 1\Big\}\\
&= 1/(j(2) - 1)\,(j(3) - 1)\ldots(j(n) - 1)j(n)
\end{aligned} \qquad [12]$$

Note that here the joint distribution of record times does not depend on F.

Now one can see from [12] that

$$P\Big\{L(n) = m\Big\} = \sum 1/(j(2) - 1)(j(3) - 1)\ldots(j(n - 1) - 1)(m - 1)m$$

where the sum is taken over all $j(2),j(3),\ldots,j(n - 1)$, such that $1 < j(2) < j(3) < \ldots < j(n - 1) < m$.

It follows from [12] also that

$$P\{L(n) = j(n)|L(n - 1) = j(n - 1), L(n - 2) = j(n - 2), \ldots,$$
$$L(2) = j(2), L(1) = 1\} = j(n - 1)/j(n)\,(j(n) - 1)$$

and

$$P\{L(n) = j|L(n - 1) = i\} = i/j(j - 1),\quad n = 2,3,\ldots,\ j > i$$

Hence we see that the sequence of record times $L(1),L(2),\ldots$ in the announced situation forms a Markov chain.

It was mentioned above that record times are closely related to the random variables N(n), since for any $n = 1,2,\ldots$ and $m = 1,2,\ldots$ the following equalities are valid:

$$P\{L(n) > m\} = P\{N(m) < n\}$$

and

$$P\{L(n) = m\} = P\{N(m - 1) = n - 1, N(m) = n\} \qquad [13]$$

Equalities [5] and [13] allow us to express the distributions of L(n) in terms of independent record indicators:

$$\begin{aligned}
P\{L(n) = m\} &= P\{N(m - 1) = n - 1, \xi_m = 1\}\\
&= P\{N(m - 1) = n - 1\}/m \qquad [14]\\
&= P\{\xi_1 + \xi_2 + \ldots \xi_{m-1} = n - 1\}/m
\end{aligned}$$

Representations [5] and [14] of N(m) and L(n) give a possibility to find the distributions of these record statistics via the Stirling numbers of the first kind, $S_n(k)$, which are defined by equalities:

$$x(x - 1)\ldots(x - n + 1) = \sum_{k\geq 0} S_n(k)x^k$$

It appears that

$$P\{N(m) = k\} = (-1)^k S_m(k)/m! = |S_m(k)|/m!,$$
$$k = 1,2,\ldots,m$$

and

$$P\{L(n) = m\} = |S_{m-1}(n - 1)|/m!,\quad m = n, n + 1, \ldots$$

Representations [5] and [14] give the following formulas for the corresponding generating functions:

$$P_m(s) = Es^{N(m)} = s(1 + s)(2 + s)\ldots(m - 1 + s)/m!$$

and

$$\begin{aligned}
Q_n(s) &= Es^{L(n)} = 1 - (1 - s)\sum_{k=0}^{n-1}(-\log(1 - s))^k/k!\\
&= \int_0^{-\log(1-s)} v^{n-1}\exp(-v)dv/(n - 1)! \qquad [15]
\end{aligned}$$

Distributions of Record Values

Let us again consider the case when $X_1,X_2,\ldots$ are independent and have a continuous d.f. F. The record value X(n) can be presented as $X_{L(n)}$, where L(n) is the corresponding

record time with a generating function [15]. One can see that then

$$P\{X(n) < x\} = P\left\{X_{L(n)} < x\right\} = P\{M(L(n)) < x\} \qquad [16]$$

where $M(n) = \max\{X_1, X_2, \ldots, X_n\}$ and $P\{M(n) < x\} = F^n(x)$.

It follows from [15] and [16] that

$$\begin{aligned} P\{X(n) < x\} &= P\{M(L(n)) < x\} \\ &= \sum_{m \geq 0} P\{M(m) < x\} P\{L(n) = m\} \\ &= \sum_{m \geq 0} F^m(x) P\{L(n) = m\} \\ &= Q_n(F(x)) = \int_0^{-\log(1-F(x))} v^{n-1} \exp(-v) dv / (n-1)! \end{aligned}$$

The following result is valid for distributions of record values.

Theorem 5

Let $X(1) < X(2) < \ldots$ be the record values in a sequence of independent random variables having a common continuous distribution function F, and let $U(1) < U(2) < \ldots$ be the record values related to the uniform distribution on the interval [0,1]. Then for any $n = 1,2,\ldots$ the random vector $(F(X(1)),\ldots,F(X(n)))$ has the same distribution as $(U(1),\ldots,U(n))$.

Corollary

Let $X(1) < X(2) < \ldots$ and $Y(1) < Y(2) < \ldots$ be, respectively, the record values in a sequence of independent random variables $X_1, X_2, \ldots$ having a common continuous distribution function F_1 and in a sequence of independent identically distributed random variables $Y_1, Y_2, \ldots$ with a continuous distribution function F_2. Then for any $n = 1,2,\ldots$ the vector $(Y(1), Y(2), \ldots, Y(n))$ has the same distribution as the vector $(H_2(X(1)), H_2(X(2)), \ldots, H_2(X(n)))$, where $H_2(x) = G_2(F_1(x))$ and G_2 is the inverse function to F_2. Analogously, the vectors $(X(1), X(2), \ldots, X(n))$ and $(H_1(Y(1)), H_1(Y(2)), \ldots, H_1(Y(n)))$, where $H_1(x) = G_1(F_2(x))$ and G_1 is the inverse function to F_1, are identically distributed.

Let us consider the partial case of record values $Z(1) < Z(2) < \ldots$ related to the standard exponential E(1) distribution (the case, when $F(x) = 1 - \exp(-x)$, $x > 0$). We get

$$P\{Z(n) < x\} = \int_0^x v^{n-1} \exp(-v) dv / (n-1)!$$

that is, in this situation Z(n) has the gamma distribution with parameter n. It means that Z(n) has the same distribution as the sum $\nu_1 + \nu_2 + \ldots + \nu_n$ of independent E(1)-distributed random variables $\nu_1, \nu_2, \ldots$. Moreover, for any $n = 1,2,\ldots$ the vector $(Z(1), Z(2), \ldots, Z(n))$ has the same distribution as the vector $(\nu_1, \nu_1 + \nu_2, \ldots, \nu_1 + \nu_2 + \ldots + \nu_n)$. It means that the vector $(Z(1), Z(2) - Z(1), \ldots, Z(n) - Z(n-1))$ consists of independent elements and each of these elements has the standard exponential E(1) distribution.

Combining the previous results, one can get the following representation for record values $X(1) < X(2) < \ldots$ related to any continuous d.f. F. Let G below denote the inverse function to F.

Representation 1

For any $n = 1,2,\ldots$

$$\begin{aligned} &(X(1), X(2), \ldots, X(n))^d \\ &\quad = (H(\nu_1), H(\nu_1 + \nu_2), \ldots, H(\nu_1 + \nu_2 + \ldots + \nu_n)) \end{aligned}$$

where $\nu_1, \nu_2, \ldots$ are independent random variables having the exponential E(1) distribution and $H(x) = G(1 - \exp(-x))$.

Taking into account the property of the exponential records, it is not difficult to obtain the joint density function $f_n(x_1, x_2, \ldots, x_n)$ of the record values $Z(1), Z(2), \ldots, Z(n)$. It appears that

$$f_n(x_1, x_2, \ldots, x_n) = \exp(-x_n), \quad \text{if } 0 < x_1 < x_2 < \ldots < x_n$$

and $f_n(x_1, x_2, \ldots, x_n) = 0$ otherwise.

In the general case, when $X_1, X_2, \ldots$ have a d.f. F and a density function f, the joint density function of the record values $X(1), X(2), \ldots, X(n)$ is given by the formula:

$$\begin{aligned} &f_n(x_1, x_2, \ldots, x_n) = r(x_1) r(x_2) \ldots r(x_n)(1 - F(x_n)), \\ &\quad x_1 < x_2 < \ldots < x_n, \end{aligned}$$

where $r(x) = f(x)/(1 - F(x))$.

Now we consider the conditional distributions

$$\begin{aligned} &\varphi(x | x_1, x_2, \ldots, x_n) \\ &\quad = P\{X(n+1) > x | X(1) = x_1, X(2) = x_2, \ldots, X(n) = x_n\}, \\ &\quad x_1 < x_2 < \ldots < x_n < x \end{aligned}$$

for record values $X(1) < X(2) < \ldots < X(n) < X(n+1)$. It appears that

$$\begin{aligned} \varphi(x | x_1, x_2, \ldots, x_n) &= P\{X(n+1) > x | X(n) = x_n\} \\ &= (1 - F(x))/(1 - F(x_n)), \; x > x_n \qquad [17] \end{aligned}$$

It is interesting that equality [17] does not need the continuity of the d.f. F. It follows from [17] that record values $X(1), X(2), \ldots$ form a Markov chain.

If we now consider discrete X's taking values $0,1,2,\ldots$ then [17] can be rewritten in the form:

$$\begin{aligned} &P\{X(n+1) > j | X(n) = m\} = P\{X > j\}/P\{X \geq m+1\}, \\ &\quad j > m \geq n - 1 \end{aligned}$$

It follows from the latter equality that in this case

$$\begin{aligned} &P\{X(1) = j_1, X(2) = j_2, \ldots, X(n) = j_n\} \\ &\quad = P\{X = j_n\} \omega(j_1) \omega(j_2) \ldots \omega(j_{n-1}), 0 \leq j_1 < j_2 < \ldots \\ &\qquad < j_{n-1} < j_n, \end{aligned}$$

where $\omega(j) = P(X = j\}/P\{X > j\}$.

The simplest discrete case is presented by the geometric distribution. The following result is valid.

Theorem 6

Let $X, X_1, X_2, \ldots$ be independent identically distributed random variables such that

$$P\{X = j\} = (1 - p) p^{j-1}, \quad j = 1, 2, \ldots, \quad 0 < p < 1$$

and $X(1) < X(2) < \ldots$ be the record values in a sequence $X_1, X_2, \ldots$. Then the interrecord values $X(1), X(2) - X(1), X(3) - X(2), \ldots$ are independent and have the same geometric distribution as X.

Distributions of *k*th Record Values

The *k*th record values X(n,k) are a natural extension of records X(n). It is interesting that distributions of the *k*th records can be expressed via distributions of the classical record values. Really, together with a sequence of independent random variables $X_1, X_2, \ldots$ having a common d.f. F, let us consider one more sequence:

$$Y_1 = \min\{X_1, X_2, \ldots, X_k\},$$
$$Y_2 = \min\{X_{k+1}, X_{k+2}, \ldots, X_{2k}\}, \ldots$$

Let now X(n,k) be the *k*th record value based on X's and Y(n) be the classical records based on the sequence $Y_1, Y_2, \ldots$. It appears that for any fixed $k = 2,3,\ldots$ and any $n = 1,2,\ldots$ the vector $(X(1,k), X(2,k), \ldots, X(n,k))$ has the same distribution as the vector $(Y(1), Y(2), \ldots, Y(n))$.

Note that this result is valid for discrete X's as well. One can obtain immediately some important results for the *k*th records taking into account the analogous results for the classical record values. For example, if Z(n,k), $n = 1,2,\ldots$ denote the *k*th records for the standard exponential distribution, then the vector $(Z(1,k), Z(2,k), \ldots, Z(n,k))$ has the same distribution as the vector $(\nu_1/k, (\nu_1+\nu_2)/k, \ldots, (\nu_1+\nu_2+\ldots+\nu_n)/k)$, where $\nu_1, \nu_2, \ldots$ are the independent exponentially E(1) distributed random variables. Hence, the following relation is valid for *k*th records related to a sequence of $X_1, X_2, \ldots$ with a continuous d.f. F.

Representation 2

For any $n = 1,2,\ldots$

$$(X(1,k), X(2,k), \ldots, X(n,k))^d = (H(\nu_1/k),\ H((\nu_1+\nu_2)/k), \ldots, H((\nu_1+\nu_2+\ldots+\nu_n)/k)$$

where $\nu_1, \nu_2, \ldots$ are independent random variables having the exponential E(1) distribution, $H(x) = G(1-\exp(-x))$ and G is the inverse function to F.

Some useful results for the *k*th records follow immediately from representation 2 and analogous results for the classical records. Say, one obtain that

$$P\{X(n,k) < x\} = \int_0^{-k\log(1-F(x))} v^{n-1}\exp(-v)dv/(n-1)!$$

and this equality is valid for any $k = 1,2,\ldots$ and any continuous d.f. F.

Theorem 7

For any $k = 1,2,\ldots$ the sequence $X(1,k), X(2,k), \ldots$ forms a Markov chain and

$$P\{X(n+1,k) > x | X(n,k) = u\} = ((1-F(x))/(1-F(u)))^k, \quad x > u$$

Different Generalizations of the Classical Records

Indeed, for more than 60 years of its history, classical records were studied carefully. During this period, there appeared a number of 'nonclassical' models (see, for example, papers (Balakrishnan et al., 1996; Deheuvels and Nevzorov, 1993, 1994; Nevzorov and Saghatelyan, 2009; Sagateljan, 2008)). Descriptions of some of such schemes are discussed below.

F^α-Scheme

Yang (1975) considered records in the sequence

$$Y_k = \max\left\{X_{k,1}, \ldots, X_{k,n(k)}\right\}, \quad k = 1,2,\ldots$$

where $\{X_{k,j}\}$, $j = 1,2,\ldots,n(k)$, $k = 1,2,\ldots$, are i.i.d. random variables with a common continuous d.f. F. It is interesting that in his model, Yang proposed to take

$$n(k) = \lambda^{k-1}n(1), \quad k = 1,2,\ldots, \quad \lambda > 0.$$

Moreover, he preferred to take $\lambda = 2^{1/9}$ for his scheme analyzing the dynamics of the Olympic records and proposing that this dynamics really depends on the growth of population of our planet. Hence this value λ was chosen in view of the fact that the world population doubled during nine 4-year periods between Olympic Games, which were organized in 1900 and 1936. His partial model initiated the appearance of the more general, the so-called F^α-scheme (see, for details, papers (Deheuvels and Nevzorov, 1993, 1994) and books (Nevzorov, 2000, 2001)), where independent random variables $X_1, X_2, \ldots$ have different differential functions, but these are of the special form:

$$F_k(x) = F^{\alpha(k)}(x), \quad k = 1,2,\ldots, \quad \alpha(k) > 0.$$

That is, coefficients $\alpha(k)$ can take any positive values. The most important property of this scheme is that the record indicators ξ_n, $n = 1,2,\ldots$, defined above save the independence property and the following equalities are valid:

$$P\{\xi_n = 1\} = \alpha(n)/(\alpha(1)+\ldots+\alpha(n)), \quad n = 1,2,\ldots$$

These properties of record indicators provided the possibility to obtain for the F^α-scheme a lot of results for random record times and record values, which are analogous to the corresponding results for the 'classical' records.

Linear Draft Model

Let $\{X_n, n \geq 1\}$ be a sequence of i.i.d. random variables with d.f. F. Suppose that we deal with random variables $Y_n = X_n + cn$, $c > 0$, $n = 1,2,\ldots$. In this situation the distributions of record indicators ξ_n are given as

$$P\{\xi_n = 1\} = P(X_j < X_n + c(n-j),\ j = 1,2,\ldots,n-1) = \int_{-\infty}^{\infty}\prod_{j=1}^{n-1}F(x+cj)dF(x)$$

Let now F(x) in this model be the Gumbel distribution with

$$F(x) = e^{-e^{-x}}, \quad -\infty < x < \infty$$

and let us consider the corresponding Linear Draft model. In this case, we have

$$P\{Y_n < x\} = P\{X_n + cn < x\} = \exp\{-\exp(-x+cn)\} = (F(x))^{\alpha(n)} \quad [18]$$

where $\alpha(n) = \exp(cn)$, $n = 1,2,\ldots$, that is, we get the partial case of the F^{α}-scheme. It means that for this partial case of the Linear Draft model, record indicators ξ_n, $n = 1,2,\ldots$, are also independent.

δ-Exceedance Record Scheme

This scheme was suggested by Balakrishnan, Balasubramanian and Panchapakesan (Balakrishnan et al., 1996). A new observation X_j is called the *δ-exceedance upper record* if it is larger than the previous record by a prefixed positive quantity δ. In this model, $L(1) = 1$ and

$$L(n+1) = \min\left\{j | j > L(n), X_j > X_{L(n)} + \delta\right\}, \quad n = 1,2,\ldots$$

he sequence $\{X_{L(n)}, n = 1,2,\ldots\}$ forms the *δ-exceedance* upper record values. If we have the sequence of i.i.d. X's having d.f. F(x) and pdf f(x), then the joint pdf of the first m upper records X(1),X(2),…,X(m) is given in this scheme by equalities:

$$f_{X(1),X(2),\ldots,X(m)}(x_1,\ldots,x_m) = \frac{f(x_1)}{1-F(x_1+\delta)}\cdots\frac{f(x_{m-1})}{1-F(x_{m-1}+\delta)}f(x_m), \quad x_j > x_{j-1}, \quad j = 2,3,\ldots,m$$

Suppose that $F(x) = 1 - e^{-x}$, $x \geq 0$, ≥ 0,then

$$f_{X(1),X(2),\ldots,X(m)}(x_1,\ldots,x_m) = e^{(m-1)\delta}e^{-x_m}, \quad x_j > x_{j-1} + \delta, \quad j = 2,3,\ldots$$

The marginal pdf of X(m) is given as

$$f_{X(m)}(x) = \frac{1}{\Gamma(m)}(x - m\delta)^{m-1}e^{-(x-m\delta)}, \quad x > m\delta$$

Thus the random variable $X(m) - m\delta$ has the gamma distribution and one can see that for any *m* the vector {X(1),X(2),…, X(m)} has the same distribution as the vector $\{Y_1, Y_1 + Y_2,\ldots, Y_1 + Y_2 + \ldots + Y_m\}$, where Y_i's are independent and have the exponential distribution with $F(x) = 1 - e^{-(x-\delta)}$, $x \geq \delta$.

From this fact, it follows that interrecord values X(m)−X(m−1), m = 2,3,…, are independent.

Records with Restrictions I

Consider now the so-called *records with restrictions*, which are rather close in some sense to the δ-exceedance record scheme. Consider the sequence of i.i.d. random variables $X_1, X_2,\ldots$ and fixed some positive constant C. We take $X(1) = X_1$ and $L(1) = 1$ as the first record value and the first upper record time correspondingly. The next record times L(n) and record values X(n) are defined as follows:

$$L(n) = \min\{j > L(n-1): X(n-1) < X_j \leq X(n-1) + C\}, \quad X(n) = X_{L(n)}, \quad n = 2,3,\ldots$$

It means that we ignore as a record the new coming observation, if it exceeds essentially the previous record value.

Suppose that the initial random variables have a common pdf f(x). It is not difficult to get the expression for the conditional pdf $f_n(x_n|x_1,x_2,\ldots,x_{n-1})$, that is the expression for the pdf of X(n) under the condition that $X(1) = x_1, X(2) = x_2,\ldots, X_{n-1} = x_{n-1}$, where $0 < x_j - x_{j-1} \leq C$, $j = 2,3,\ldots,n-1$, are fixed. One obtains in this case that

$$f_n(x_n|x_1,x_2,\ldots,x_{n-1}) = f(x_n) - (F(x_{n-1}+C) - F(x_{n-1})) \quad [19]$$

if $x_{n-1} < x_n \leq x_{n-1} + C$, and $f_n(x_n|x_1,x_2,\ldots,x_{n-1}) = 0$ otherwise.

These equalities allow to find the corresponding relations for probability density functions $f_{n-1}(x)$ and $f_n(x)$ of random variables X(n−1) and X(n):

$$f_n(x) = f(x)\int_{x-C}^{x}(f_{n-1}(u)/(F(u+C) - F(u)))du, \quad n = 2,3,\ldots \quad [20]$$

From [20] one gets that the joint pdf $f_n(x_1,x_2,\ldots,x_n)$ of record values X(1),X(2),…,X(n) has the following form:

$$f_n(x_1,x_2,\ldots,x_n) = f(x_1)\frac{f(x_2)}{(F(x_1+C) - F(x_1))}\cdots\frac{f(x_n)}{(F(x_{n-1}+C) - F(x_{n-1}))} \quad [21]$$

if $x_1 < x_2 \leq x_1 + C$, $x_2 < x_3 \leq x_2 + C,\ldots, x_{n-1} < x_n \leq x_{n-1} + C$, and $f_n(x_1,x_2,\ldots,x_n) = 0$ otherwise.

These relations can be simplified essentially for the case of exponential distributions of X's.

Let us consider the sequence $Z_1, Z_2,\ldots$ of i.i.d. random variables having the standard E(1) d.f. $F(x) = \max\{0, 1-\exp(-x)\}$. Consider also $Z_0 = 0$. Denote the corresponding record (with the restriction $C > 0$) values and record times as

$$0 = Z(0) < Z(1) < Z(2) < \ldots \quad \text{and}$$
$$0 = T(0) < T(1) < T(2) < \ldots$$

One gets from [21] that the joint pdf of random variables Z(1),Z(2),…,Z(n) is given as

$$f_n(x_1,x_2,\ldots,x_n) = \exp(-x_n)/(1-\exp(-C))^n \quad [22]$$

if $0 < x_1 \leq C$, $x_1 < x_2 \leq x_1 + C,\ldots, x_{n-1} < x_n \leq x_{n-1} + C$, and $f_n(x_1,x_2,\ldots,x_n) = 0$ otherwise.

It follows from [22] that the joint pdf $g(v_1,v_2,\ldots,v_n)$ for differences

$$V(1) = Z(1) - Z(0), V(2) = Z(2) - Z(1), \ldots, V(n) = Z(n) - Z(n-1)$$

has the form

$$g(v_1,v_2,\ldots,v_n) = \exp\{-(v_1+v_2+\ldots+v_n)\}/(1-\exp(-C))^n, \quad 0 \leq v_1 \leq C, \ldots, 0 \leq v_n \leq C \quad [23]$$

This formula allows us to state that interrecord values V(1),V(2), …, V(n) are independent and identically distributed with the pdf

$$g(x) = \exp(-x)/(1-\exp(-C)), \quad \text{if } 0 \leq x \leq C, \text{ and } g(x) = 0, \quad \text{otherwise}$$

It means that vectors

$$\{Z(1), Z(2), \ldots, Z(n)\} \text{ and } \{W_1, W_1 + W_2, \ldots, W_1 + W_2 + \ldots + W_n\}$$

where independent random variables $W_1, W_2, \ldots, W_n$ have the pdf [23], are identically distributed. Thus the exponential random value Z(n) is presented as the sum of n i.i.d. random variables.

Note that the means and the variances of $W_1, W_2, \ldots$ are given as

$$a(c) = EW_k = \left(1 - (1+C)e^{-C}\right)/\left(1 - e^{-C}\right)$$

and

$$\sigma^2(C) = DV_k = (1 - (2 + C^2)e^{-C} + e^{-2C})/(1 - e^{-C})^2, \quad k = 1, 2, \ldots$$

It is possible based on these facts to obtain, in particular, different limit theorems for Z(n). For example, it follows immediately that random variables $(Z(n) - na(c))/\sigma(c)n^{1/2}$ tend as $n \to \infty$ to the standard normal distribution. Indeed, all results formulated above for the exponential E(1) random variables $Z_1, Z_2, \ldots$, can be rewritten analogously for the general case, when initial random variables have pdf's:

$$f(\alpha, \lambda) = \lambda \exp(-\lambda(x - \alpha)), \quad x \geq \alpha \quad \text{where} \quad \lambda > 0 \quad \text{and} \quad -\infty < \alpha < \infty$$

Records with Restrictions II

The next scheme is very close to the previous one. Now we also fix some constant $C > 0$, which determines the acceptable rate of exceeding of the previous record value. The discrepancy of these two schemes is the following. In the second case, we do not ignore the observations, which are essentially greater than the previous record value X(n). In this situation, we simply determine the new record value X(n + 1) as X(n) + C. In the case when the new coming observation belongs to the interval (X(n),X(n) + C), it is announced as the record value X(n + 1).

If we again consider the initial independent E(1)-distributed random variables (with pdf $f(x) = \exp(-x)$, $x \geq 0$) $Z_1, Z_2, \ldots$ and denote the records with such type of restrictions as $0 = Z(0) < Z(1) < Z(2) < \ldots$, then arguments analogous to those, which are given in the previous model, show that differences (interrecord values) $V_k = Z(k) - Z(k-1)$, $k = 1, 2, \ldots$, are also independent. In this case, we get that

$$P\{V_k < x\} = 1 - \exp(-x), \quad \text{if } 0 \leq x \leq C, \text{ and} \quad P\{V_k < x\} = 1, \quad \text{if } x > C. \qquad [24]$$

In particular

$$P\{V_k = C\} = \exp(-C), \quad k = 1, 2, \ldots$$

One can see that in this record scheme for any $n = 1, 2, \ldots$ the distribution of the vector $\{Z(1), Z(2), \ldots, Z(n)\}$ coincides with the distribution of the vector $\{V_1, V_1 + V_2, \ldots, V_1 + V_2 + \ldots + V_n\}$, where $V_1, V_2, \ldots$ are i.i.d. random variables having the d.f. [24].

Records with Confirmation

One more nonclassical record scheme – the so-called 'records with confirmation' (confirmed records), was considered in Sagateljan (2008) and Nevzorov and Saghatelyan (2009). In the simple option of this scheme to determine a new record value X(n + 1), one must wait for appearance of k (k is fixed number) observations, which will be greater than the previous record value X(n), and only after this event it is possible to determine X(n + 1) as the maximal value among these k observations. This scheme is useful in the situation when among X's, which have some fixed distribution, can appear an observation having another distribution (contamination of the original sample). The following new result generalizes this case. Let us consider the situation, when a new record will coincide with the mth ($1 \leq m \leq k$) in order of observations taken from k random variables, which are greater than the previous record value. The reason why we consider here the case when m can be less than k is rather simple. For example, imagine that we know that the given sample can be contaminated with some outliers and we expect that these outliers are presented in the sample by the 'top' observations. Hence, it is natural to delete these extraneous observations from the further consideration.

As above, the most interesting case here is connected again with the exponential distribution. The following result is valid.

Theorem 8

Let $F(x) = \max\{0, 1 - \exp(-x)\}$, and $1 \leq m \leq k$, defined above, be fixed. Then for any $n = 1, 2, \ldots$ the following equality holds:

$$\widehat{X}(n+1)^d = \widehat{X}(n) + X_1^{(n)}/k + \ldots + X_m^{(n)}/(k - m + 1) \qquad [25]$$

where $\widehat{X}(n), X_1^{(n)}, \ldots, X_m^{(n)}$ are independent and $P\{X_j^{(n)} < x\} = \max\{0, 1 - \exp(-x)\}$, $1 \leq j \leq k$.

Corollary

It follows from Theorem 8, that

$$\widehat{X}(n)^d = \mu_1/k + \mu_2/(k-1) + \ldots + \mu_m/(k - m + 1) \qquad [26]$$

where $\mu_1, \mu_2, \ldots$ are independent gamma-distributed random variables.

From this theorem, which is formulated for the exponential record values, it can be obtained (using the standard methods from the theory of records) that a set of all possible types of the limit distributions G(x) for the records with confirmations coincides with the corresponding set for the classical records:

$$G_i(x) = \Phi(-\ln(-\ln H_i(x))), \quad i = 1, 2, 3, \qquad [27]$$

where

$$H_1(x) = \exp\{-\exp(-x)\}, \quad -\infty < x < \infty$$

$$H_2(x) = 0, \text{ if } x < 0, \text{ and } H_2(x) = \exp\{-x^{-\delta}\}, \text{ if } x > 0, \ \delta > 0$$

$$H_3(x) = \exp\{-(-x)^{\delta}\}, \quad \text{if } x < 0, \ \delta > 0, \quad \text{and}$$

$$H_3(x) = 1, \quad \text{if } x > 0,$$

and $\Phi(x)$ is the normal N(0,1) distribution function.

Indeed, the centering and normalizing constants in this situation will differ from the corresponding constants for the classical records.

A more complete theory of records is given in monographs (Ahsanullah, 1988, 1995, 2004; Ahsanullah and Nevzorov, 2001; Arnold et al., 1998; Nevzorov, 2000, 2001). Different results for record values can be found in the Bibliography section.

Abstract

The organizational context of medical practice changed substantially over the past half century, resulting in new opportunities and a more favorable environment for the evolution of allied and nonphysician health professionals. This article chronicles the organizational developments leading to the growth in nonphysician health professions and the changing medical division of labor. Recent trends in nursing, the rise of advanced practice nurses and physician assistants (PAs), and the status of physical and occupational therapists are examined.

The Changing Context of Health Care

The organizational complexity of health care, including the rise of physician group practices and decline of the solo family physician, the entrance of for-profit hospitals and health systems, and the growing dominance of professional managers without a clinical background, has changed the nature of the patient–provider relationship (Starr, 1982). These changes coupled with societal pressures from better informed patients have resulted in the evolution of the physician role and relationship with patients, from one of dominance and authority to one of collaborator and shared-decision maker (Mechanic, 1986). Powerful stakeholders, including allied health professionals, nonphysician providers, and administrators have entered the system, often with a goal that differs from that of the physician. Hospital administrators, motivated to find cost-effective ways to deliver health care, began looking to nonphysician providers to expand their role in the provision of health services. This shift in provider configuration represents a trend occurring internationally.

With the global rise of health care costs, the emergence of national governments' involvement in the delivery and management of health care has grown extensively since the twentieth century. This has been evidenced in the United States through public policy with programs like Medicare and Medicaid, which provide insurance for the elderly, poor, and disabled. European nations have experienced government involvement in the form of austerity initiatives, designed to trim deficits and reduce services, which has led to public uncertainty about the future of health care in these nations.

Advances in biomedical research and technology, expansion of health insurance, increased incidence of chronic conditions, and expanding social definitions of the boundaries of medical care all contributed to increased utilization of health services and changing patterns of care. These changes fostered the development of an expanded division of medical labor in which a new group of health professionals emerged to complement and compete with physicians in the delivery of a broader array of health services. At the beginning of the twentieth century, physicians accounted for about one in three health care workers; by the 1980s, the comparable ratio was about 1 in 16 (Mechanic, 1983). This trend has continued into the twenty-first century with physicians accounting for a smaller and smaller share of the total health care workforce.

Changing Disease Patterns

Progress in medical science including antibiotics and vaccines as well as improved standards of living contributed to shifting the burden of illness from acute, infectious illnesses to complex, chronic conditions. While advances in modern medicine have produced important treatments for chronic illnesses, most have resulted in technologies that extend life but do not cure the underlying disease. Examples include long-term renal dialysis for the treatment of kidney failure, antiretroviral drugs that extend the lives of people with acquired immunodeficiency syndrome, and antineoplastic agents that extend survival in people with certain cancers.

Chronic conditions are accompanied by a myriad of functional limitations and social support needs that fall outside the conventional definition of medical practice. Nurses, social workers, occupational therapists, physical therapists, and other nonphysician health professionals have demonstrated interest and expertise in helping the chronically ill and frail elderly manage the sequelae of chronic conditions and medical treatments, thus creating new roles for themselves in the medical division of labor.

Accessibility of Health Care Services

Along with the technological and medical developments of the mid-twentieth and early twenty-first centuries came increasingly expensive, complex, inefficient, and unsustainable health care systems. Calls for comprehensive health reform ensued in many countries. After decades of public debate, the United States finally passed incremental health insurance reform, the Patient Protection and Affordable Care Act (PPACA), under the Obama administration, which was signed into law in early 2010. The PPACA required sweeping changes to the way health care is accessed and paid for by individuals and employers in the United States. Many of the components of the health reform directly impact nonphysician health care providers. Namely, a large cadre of newly insured citizens will be accessing

the health care system. Although the patterns of use and types of providers needed to accommodate an expanded patient population remain unknown, nonphysician providers are poised with the skills and knowledge to care for this newly insured group.

Organizational Changes Conducive to Expansion of Nonphysician Professions

As a result of the PPACA, approximately 30 million of the estimated 50 million uninsured people in the United States will have improved access to health care providers as of 2014. Many of the newly insured are likely to seek primary care services, which may be problematic because primary care physicians are in short supply due to a number of factors, including migration to specialty practices and changing practice patterns including less willingness of physicians to work long hours as in years past. Changes in reimbursement that favor specialty practice and heavy financial debt associated with medical school in the United States have contributed to a smaller share of US physicians electing careers in primary care. As more physicians gravitate toward specialized medicine, opportunities are increasing for nonphysician providers to enter the market for primary care services.

Globally, the health care environment has never been more receptive to nonphysician providers. Americans are not unique in their struggle with an increasingly costly, fragmented, and inequitable health care system. Rich and poor countries alike are facing the challenges associated with aging populations and increased demand for health care services without adequately trained, distributed, and diverse numbers of health care providers (World Health Organization, 2006). The Lancet Commission on the Future of Health Professions, written by a team of interdisciplinary experts, recommended a series of action items and reforms to redesign health provider's education, addressing the gaps that exist both in and across countries. The report highlights competency-based curricula, interprofessional education, use of information technology systems, and creation of global networks to share knowledge and resources as key pieces to a transformed education system for health professionals (Frenk et al., 2010).

Allied Health Professionals

The allied health workforce is diverse in term of roles, settings of practice, and educational requirements. Over 200 occupations fall under the 'allied health' umbrella, which contributes to the difficulty in distilling a singular definition or a complete list of allied health professionals. The Association of Schools of Allied Health Professions describes allied health professionals as being engaged in the delivery of health services such as evaluation and prevention of disease, nutritional services, and rehabilitation. Typically, physicians, dentists, nurses, pharmacists, chiropractors, and social workers are excluded from definitions of allied health because these disciplines are often educated in identifiable professional schools, whereas the other disciplines that comprise allied health professionals may be educated together. However, it is still common for the term allied health professionals to be used to refer to all nonphysician health professionals.

Allied health professionals fill a critical role in modern health care and are integral members of the health care team. Because many of the occupations have developed as a result of technological advances such as ultrasound technologists, the group of allied health professionals is constantly evolving and expanding. Two of the group's largest and oldest professions are occupational and physical therapists and are detailed in the following section.

Evolution of Occupational and Physical Therapy

Occupational therapy traces its origins back 200 years to a French physician's observation that mental patients given menial tasks to perform improved in functional capacity faster than those who were idle. At the end of the eighteenth century, American physician Benjamin Rush introduced work as a treatment for mentally ill patients at Philadelphia's Pennsylvania Hospital, and in 1906, the first training course for occupational therapists was established in Boston (Institute of Medicine, 1989). World War I created a demand for rehabilitation of large numbers of injured soldiers, which served as a major impetus for expanding the scope of practice of occupational therapy to physically as well as mentally disabled persons, and for establishing the new occupation of physical therapy.

Education and Characteristics

The two world wars stimulated the growth of physical and occupational therapists and the early recruits to both occupations were mainly women. Over time they have remained predominantly female occupations, although about a third of physical therapists are men compared with about 10% for nurses and occupational therapists. The first American training program in physical therapy began in 1917, as a short course for women aides. The success of these aides following World War I resulted in federal funding to increase the supply of therapists during World War II through accelerated programs to train college graduates in related fields such as physical education for roles in therapy. University-based degree-granting programs in physical therapy were established concurrently. Physical therapy has thus been a university-based educational program almost from its inception.

In 1979, the American Physical Therapy Association advocated for graduate level preparation for the profession by 1990. Although it took longer than perhaps desired, by 1 January 2016, the doctor of physical therapy (DPT) will be the required degree for all entry-level physical therapy programs. While therapists with a baccalaureate degree may still practice, the changes in educational standards have not been limited to future cohorts of students; many licensed practitioners have earned postprofessional DPT degrees or a transition DPT approximately 11 000 as of 2010. Like

registered nurses (RNs), physical therapists must be a graduate of an accredited physical therapy education program and pass the licensure exam prior to practicing. Physical therapists must be licensed by the state in which they practice and must renew their license on a regular basis. Physical therapy does not support career mobility from the physical therapy aide category to the professional category and has established nonoverlapping educational requirements for the two groups thus avoiding the problem nursing has faced. Physical therapy has also developed viable options for private practice, which allows the occupation to continue to evolve independently, to some extent, from institutional managerial control of salaried practice. Physical therapy is considered to be more visible and autonomous than occupational therapy for these reasons (Institute of Medicine, 1989).

The first formal 'professional' standards for education in occupational therapy were established in 1923, as 12-month training programs for high school graduates, in contrast to physical therapy, which moved directly to university-based education. As of January 2007, however, the entry-level degree for occupational therapists is postbaccalaureate, either a master's or doctoral degree. Licensure is state based; requirements include graduation from an accredited occupational therapy program, fieldwork, and passing the certification examination before obtaining a license as an occupational therapist. Technical training as an occupational therapy assistant occurs primarily in community colleges and in some 4-year university settings. Graduating from an accredited program and passing a licensing exam are also requirements from occupational therapy assistants.

Roles and Work Settings

Physical therapists plan and administer treatment to relieve pain, improve functional mobility, and limit the physical disability of people with injury or illness. Increasingly, physical therapists specialize within an area of practice such as children or orthopedics and sports medicine. The rapid growth in joint replacements overall and to younger patients as medical technology has advanced has significantly increased the demand for physical therapists in recent years. Most physical therapists work in private offices, clinics, or hospitals; other employers include home health agencies and nursing or residential care facilities.

Occupational therapists promote learning of skills necessary to perform daily tasks, diminish or correct pathology, and promote and maintain health. Occupational therapy focuses on both mental and physical disabilities, and some occupational therapists specialize in particular age groups such as the elderly. Occupational therapists working with the mentally ill or disabled in institutional and community-based settings typically provide activities that help their patients learn to cope with daily stresses and manage their work and leisure time more efficiently (Institute of Medicine, 1989). Like physical therapists, most occupational therapists work in hospitals and private offices, although nursing homes and home health care agencies are other employers.

Nursing

Nursing is the largest of the health professions with approximately 3 million RNs in the United States and roughly 19 million nurses and midwives worldwide. The American Nurses' Association Social Policy Statement (2010) defines the nursing profession as "… the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations" (American Nurses Association, 2010). This broad definition coupled with a valuable set of skills, knowledge, and public trust has allowed for role expansion of nurses both domestically and internationally.

Historical Perspectives

Modern nursing dates back to mid-nineteenth century, England, when hospitals were disorganized, unsanitary, staffed by unskilled workers, and were generally held in low esteem. Only the destitute sought help in hospitals, except in wartime. Florence Nightingale, a wealthy and educated English woman, accepted the challenge of bringing order to military hospitals during the Crimean War and in doing so began a social experiment that would change the nature of hospitals worldwide. Nightingale identified trained nurses as the vehicle for transforming hospitals but she recognized that nurses capable of skilled work and responsible ward management would have to be recruited from the better educated classes. To legitimize the work of nursing to middle to upper class women, she drew on the well-respected traditions of religious education and military-style authority. Young nurses motivated by a sense of dedication and service to mankind worked long hours for low wages under strict discipline (Abel-Smith, 1960).

Nightingale capitalized on the opportunity created by the war to not only become the founder of modern nursing, but also to become one of the first to use proportional statistics (Cohen, 1984). By tracking deaths by cause in military hospitals in Crimea, she demonstrated that more soldiers died of hospital environmental causes than of injuries received in battle. Nightingale's social position and statistical prowess forged a new future for hospitals and the nurses who worked in them.

Vestiges of History in Contemporary Nursing Roles

Nursing's history leaves a legacy that gives contemporary professional nurses special legitimacy in the medical division of labor and a high level of public trust. However, that same legacy creates barriers to the continued evolution of the profession of nursing in contemporary health care. Nursing developed as an ancillary occupation supportive to physicians. While nurses gained much of their professional status and public legitimacy from their close association with physicians, their subordinate status relative to medicine has hindered their quest for greater autonomy (Freidson, 1970). Medical dominance over nurses is linked to the organizational frame of the modern hospital where the majority of nurses practice

and where physicians exercise considerable professional authority. Indeed, nursing's quest for professional autonomy was not realized to any great extent until they began to practice in larger numbers and in a broader array of roles outside the hospital.

The association of early nurse training with religious orders has reinforced a continuing expectation of service and charity. These attributes are no longer valued as highly in Western culture, and no longer serve as sufficient motivating forces to recruit and retain professional nurses. Despite a shift from caring and nurturing functions to more technological responsibilities akin to those associated with male roles in other occupations, nursing has retained a feminine image and is thus subject to sex-role stereotyping and sex discrimination in professional relationships and labor practices. Although the nursing profession remains largely white and female dominated (U.S. Department of Health and Human Services, 2008), more gender, racial, and ethnic diversity has become a priority (Institute of Medicine, 2011).

Nursing Education

Professional nursing education has undergone a dramatic transformation since the 1970s, that is still underway globally (Lynaugh and Brush, 1996). Nursing education developed in hospital apprentice-like programs with a large service component. Until the Great Depression forced many graduate nurses into hospital employment, hospital nursing care was supplied largely by students in training. Leaders in American nursing advocated early in the twentieth century for the standardization of nursing education within institutions of higher education and a baccalaureate degree as minimum entry to practice, with the Goldmark Report being published in 1923. The Flexner Report (1910) had brought about similar reform in medical education in the United States. Subsequent reports and commissions supported the recommendation culminating in the American Nurses Association in the late 1970s setting 1985 as the target year for requiring the baccalaureate degree as minimum entry into practice. While progress has been made to this end, the new century dawned without this goal having been achieved in the United States, although other countries including Australia, New Zealand, Iceland, Chile, Norway, and Spain have successfully implemented minimum academic degree requirement for new entrants into nursing.

Nursing has been described as an incompletely closed profession because of its inability to set a minimum educational requirement (Freidson, 1970). Three generic types of education programs prepare professional nurses: 3-year hospital diploma programs, 2-year associate degree programs, and 4-year college or university programs. Following graduation from an accredited program, a state licensing exam must be passed in order to practice as an RN. Neither employers nor legal practice acts distinguish between professional nurses by type of education. The proportion of US nurses whose highest educational preparation was a diploma has dramatically decreased, while community college programs offering associate degrees increased. From 1980 to 2008, for example, the percentage of nurses educated at the diploma level decreased from 55 to 14% and associate degrees rose from 18 to 36%. In comparison, the rise of baccalaureate-prepared nurses was not as dramatic, only increasing from 22 to 37% in the same time frame. In 2008, only 13% of nurses held a master's degree, doctoral degree, or higher (Institute of Medicine, 2011). Multiple entry pathways into nursing have led to confusion for the public, as well as other health care professionals. The history of nursing is intertwined with the history of nursing education and nursing's quest for a professional identity (Allen et al., 2006). Although the goal of requiring a bachelor's degree as a minimum entry into practice has not been achieved in the United States, calls to standardize entry into practice continue.

In 2010, the Institute of Medicine released the landmark report, *The Future of Nursing*, which advocated for increasing the number of baccalaureate-prepared nurses in the workforce to 80% by 2020, also known as '80 by 20' (Institute of Medicine, 2011). Empirical research has identified a clear association between higher levels of nurse education and improved patient outcomes, including mortality (Aiken et al., 2011). Achieving '80 by 20' depends upon a variety of mechanisms including the creation of seamless pathways to Bachelor of Science in Nursing (BSN) education, funding BSN capacity expansion, increasing profiles in nursing leadership, establishing employer incentive programs, and enhancing diversity in the workforce.

Advanced Practice Nurses and Physician Assistants

Nurse practitioners (NPs), also known as advanced practice registered nurses (APRNs), and physician assistants (PAs) are two relatively new additions to the medical division of labor, both originating in the United States in the 1960s. NPs represent more of an evolution in the profession of nursing than a distinct new occupation while PAs constitute a new nonphysician profession. An APRN is an RN with a postgraduate degree and continued education in nursing. APRNs demonstrate effective integration of theory, clinical practice, and experience with degrees of autonomy in patient interventions. APRN education supports four recognized areas of specialization: nurse anesthetists (Certified Registered Nurse Anesthetists/CRNAs), nurse midwives (Certified Nurse Midwives), clinical nurse specialists, and NPs. In contrast, PAs are interdependent semiautonomous clinicians who practice in collaboration with physicians (Schneller, 1978). The impetus for the development of PAs and NPs was a shortage of primary care in the United States. However, over time PAs have followed the trends in physician specialization and now over half of PAs are in specialty practice. NPs are more likely to practice in primary care settings and care for underserved populations.

Evolution of NP and PA

While nursing's growth is strongly tied to the development of the modern hospital, nurses have a long and distinguished history in public health and home care, settings in which they exercised considerable autonomy and professional leadership. Lillian Wald invented the term 'public health nurse' in 1893 to describe a role for a nurse that was a combination of health promotion, illness care, and social reform (Buhler-Wilkerson, 1993). Public health nursing and public health in general

underwent substantial erosion in the United States with the rise of health insurance after World War II. However, the foundation for the emergence of NPs was the legacy of public health nursing.

In the case of NPs, however, these factors created a favorable environment for expanding the scope of nursing practice that had long been advocated by nursing's leaders and that was exemplified by the early public health nurses (Fairman, 2008). Thus, NPs are really not new at all but nurses with legally sanctioned expanded scope of practice including some domains formerly controlled solely by physicians, such as drug prescription authority (Lynaugh and Brush, 1996; Mezey et al., 2003).

The evolution of the development of PAs is often linked to a perceived shortage of generalist physicians in the United States in the 1960s and the market demand for physician substitutes. The PA profession was first proposed in 1961 when it was recommended to the American Medical Association to "create two new groups of assistants to doctors from nonmedical and nonnursing personnel." Most initial recruits to PA programs were experienced medical corps personnel and the initial training programs were short-term on-the-job training. While the profession was predominantly male in its inception, it is now almost equally male and female, and the most recent graduating classes are over 60% female (Hooker and Cawley, 1997). The early programs were located at medical schools but did not have academic standing or lead to degrees. Over time, degree-granting programs have been incorporated into schools of allied health.

Education and Characteristics

In the United States, a master's degree (or doctoral degree beginning in 2015 for CRNAs) is required for certification in advanced practice nursing. Education of the NP has been rapidly incorporated into the large existing university-based infrastructure of schools of nursing. Enrollments in NP programs have grown steadily and by 2009 there were about 150 000 NPs in the United States, with schools producing roughly 5000–6000 new NPs per year.

PA education is generally 24 months in length, following the acquisition of a bachelor's degree. A major difference between PAs and NPs is that PAs have accepted a legally dependent role working under the direction of a physician while NPs have fought for and obtained a legal scope of practice that does not require physician supervision (Sage and Aiken, 1997). In the United States, the profession is represented by the American Academy of Physician Assistants. Similar providers have different titles in other countries such as clinical officers in Africa, assistant medical officers in Malaysia, and assistant doctors in China. Upon graduation for accredited training programs, PAs must pass the national certifying examination of the National Commission on Certification of PAs, an independent accrediting agency, after which they must complete continuing medical education every 2 years and pass a recertification examination every 6 years in the United States.

Essentially, the role of the NP and the PA is quite similar in regard to scope of practice, function, and role as both professional groups can diagnose, treat, and prescribe. The training of each group varies in that PAs are trained under a generalist curriculum, modeled after medical school programs. All PAs learn primary care and then rotate through major specialty clinicals while in training. NPs are traditionally trained in a focused approach, specializing in a specific area of medicine or with focus on a specific population.

Both the NP and PA professions constitute an evolving health care workforce and the face of a new generation of health care workers. In most countries in which the role of an APRN exists, NPs provide a range of services that may otherwise be performed by physicians in primary care, including diagnostics, screenings, prescriptions of pharmaceuticals or medical tests, prevention and health education activities, the monitoring of patients with chronic illnesses, and care coordination (Delamaire and Lafortune, 2010). The education and training requirements to become an APRN vary both within and across countries; however, most require a graduate degree in nursing or a master's degree. The United States was the first country to introduce the right for nurses to prescribe drugs in the mid-1970s, followed by the United Kingdom, Australia, and Taiwan in the 1990s. The role of the NP has expanded dramatically around the world since its introduction in the 1960s, but a continued need for the development of the role to address health promotion, disease prevention, and to provide for evidence-based care to underserved global populations is warranted (Savrin, 2009). Worldwide, countries are exploring the concept of the PA as an efficient and quick means to train and employ highly autonomous health care workers to serve their populations. Professional organizations are proactively providing information about PAs within the global community and several countries are now utilizing US-trained PAs in pilot programs or in established training curriculums. A number of PA programs have affiliation agreements with institutions outside of the United States to host PAs for clinical training. With over 100 training programs globally, the PA model can be adapted to the needs of specific nations.

Roles and Work Settings

NPs and PAs provide generalist or specialty care including routine physical assessment, treatment of uncomplicated episodic illness, continuing care for persons with stable chronic conditions, and acute care in hospital settings. The role of the NP was developed in 1965 due to a need for a cost-effective avenue for increased access in rural communities in the state of Colorado. NP training programs developed in the 1970s with certification programs followed by master's level curriculum. The role of the NP has continued to expand in part due to legislative victories leading to an increasing independent role in practice. Such legislative initiatives include the NP being recognized for third party reimbursement, along with the addition of prescriptive authority. By the turn of the twenty-first century, NP programs had entered the mainstream of graduate nursing education.

The scope of practice that defines boundaries for NPs and PAs is determined by state licensing boards, as no federal regulation exists. Regulations vary widely and tend to focus on standards for physician oversight, prescribing authority and ratio of physicians to practitioners. Consequently, this makes

policy and regulation developments complex when distinguishing the role of physician providers versus the nonphysician health care workforce. As of 2013, 11 states allow NPs to practice independently of a physician, but the majority of states limit nonphysician providers' ability to prescribe medications. Although state boards of nursing have successfully lobbied to define a legal scope of autonomous practice for NPs, attempts by physicians to exert control over their practice and remuneration is a continuing source of conflict (Sage and Aiken, 1997). Licensing boards in the United States recognize PAs as practitioners authorized to perform medical tasks delegated to them by physicians. Legislation empowers PAs to perform any clinical task within the scope of practice and sanctioned by their collaborating and supervising physician (Mittman et al., 2002).

The passage of the PPACA marks a significant opportunity for the nursing profession to impact the delivery of health care. The designation of nurse-managed health clinics as eligible for federal funding will allow nurses to be trained in primary care and will increase access to citizens. The role of nursing will be highlighted by a number of programs directed at transitional and chronic care management, a role to which nurses are adeptly skilled. Nurses and nonphysician providers are tasked with the role of using the existing legislation to showcase the value of the professions in providing cost-effective, high-quality care to the population.

Global Perspectives

Maldistribution of health care providers is universal. Globally, few countries escape challenges in the number, quality, and skill mix of their health care workers (Chen et al., 2004). There is an estimated need for 6 million new health care workers, physicians, nurses, and midwives, based on the World Health Organization's goal of 2.3 health workers per 1000 people. Sub-Saharan Africa accounts for only 3% of the world's health care workers yet carries nearly a quarter of the disease burden compared to the Americas, which only account for 10% of the global disease burden and claim 37% of the health care workers (World Health Organization, 2006).

Allied health workers provide much of the medical care in poor countries but are in short supply and often poorly trained. The potential of nurses and APRNs to improve access to and quality of health care in developing countries is well recognized. However, many countries have insufficient resources to create employment opportunities for qualified nurses.

The inequitable distribution of health workers is seen in the nursing population, with nurses migrating from poor countries to wealthier ones. Low salaries, poor working conditions, lack of health care infrastructure, and social stigma associated with the profession are some reasons that nurse migration is widespread. Once nurses leave their native country, the working conditions become even worse for the nurses remaining, perpetuating a cycle of migration (Kaelin, 2011).

Thus, nonphysician providers and allied health occupations have good prospects for future growth in developing countries as well as in the sophisticated and highly technological health systems of industrialized countries.

Abstract

This article provides a critical overview of the changing role of the nonprofit sector, its definition, its evolving functions in the last few decades such as advocacy and empowerment, existing diversity within the sector, and various challenges that it faces in the twenty-first century.

Introduction: Scale and Diversity of the Nonprofit Sector

Nonprofit organizations exist worldwide and there is a huge range of diversity in activities that they take on and the scale of their operations. Much of the early research in the 1970s was done in the United States, but since the 1980s the study of nonprofit sectors has grown rapidly in other countries around the world especially in the developing world. Research has shown that the scope and dimensions of nonprofit organizations vary within and between countries, regions, cities, and neighborhoods. Nationally, too, nonprofit sectors vary in every country in terms of the numbers of nonprofit organizations, the services they provide, their revenues, and their employment (Salamon et al., 1999). Most of this research has involved case studies or comparisons among a small number of regions within each country, undoubtedly because the difficulty of acquiring data on these areas, the diversity of nongovernmental organizations (NGOs), and the diverse contextual factors that exist in their operations make generalizations difficult (see Desai and Preston, 2000).

While philanthropy and nonprofit organizations have long been considered in a number of social science disciplines, the nonprofit sector as a distinct field of study is a fairly recent phenomenon. Sparked mainly by a growing recognition of the importance of the nonprofit sector and debates about the future of the welfare state, interest in the nature of nonprofit organizations (also known as the third sector) has grown rapidly. At the global level in the 1980s significant growth took place in nonprofit organizations; this growth was stimulated in part by welfare state reorganization, which resulted in the substitution of private service provision for government services. Growth in nonprofit organizations in the 1980s was also due to increased activity in the areas of development and environmentalism, the rise in middle-class expectations, and improvements in communication technology. For example this rise is seen in the number of NGOs operating in the United States, estimated to be 1.5 million (http://www.humanrights.gov/2012/01/12/fact-sheet-non-governmental-organizations-ngos-in-the-united-states/ (visited on 26.10.13.)); on the other hand in India that number is estimated to have been around 3.3 million NGOs in 2009 (http://southasia.oneworld.net/news/india-more-ngos-than-schools-and-health-centres#.Une35xC8bX8 (visited on 26.10.13.)).

As a result NGOs are difficult to define (see the broad definition below) and classify and hence many different classifications are in use. The most commonly used framework of classification includes orientation (referring to the type of activities it takes on as its main focus, which might include human rights, combating child poverty, environmental, or development work) and level of operation (indicating the scale at which an organization works, such as local, regional, national, or international) (Vakil, 1997). Nonprofit research has shown that the diversity and scale can be due to broad societal patterns as well as factors that are more specific and contextual to that location or region. In the last two decades lots of research has taken place on NGOs in both the North and South to understand their functioning and explore patterns of their behavior. Broad patterns include historical development and social, economic, and political factors such as class relationships; state–society interactions; the nature of the legal environment; and the legitimacy of and trust in collective action through nongovernment. More specific factors include government policy about welfare funding and service delivery; the degree of social heterogeneity; the generosity of particular segments of the community; the needs and desires for public or semipublic goods, by either disadvantaged or middle/upper-class citizens; and the resources available for nonprofit organizations, including money, labor, and social entrepreneurs.

Relatively few systematic spatial studies of nonprofit organizations have been carried out at the neighborhood level. Some neighborhood studies have been descriptive and have used geographical information systems techniques to relate providers and needs spatially, within or across neighborhoods in metropolitan areas. In a typical example, a project by the Center on Nonprofits and Philanthropy at the Urban Institute used a spatial analysis to examine the relationships between the nonprofits that serve families and children and the socioeconomic characteristics of three low-income neighborhoods in the District of Columbia. The purpose was to show how neighborhood environments, including the presence of nonprofit organizations, affected the well-being of community residents (De Vita et al., 2000). A study of nonprofits across Dallas, Texas (Bielefeld et al., 1997) found that nonprofit organizations were more strongly influenced by demographic factors such as resources available locally and the specific need of the community in their immediate areas, than by the demographic characters of areas farther afield. These results indicate that the nonprofit sector is closely tied to the dynamics

of local communities (e.g., their levels of involvement and participation in programs and their own initiatives). Similar findings were reached by Desai (1999; Desai and Preston, 2000) in Mumbai, India. In Bangladesh for example NGOs have actively promoted neighborhood self-help savings groups, e.g., Grameen Bank or Kudumbashree in Kerala (India). Local formal savings or microfinance groups or microenterprises have emerged in communities as an approach to eradicate poverty supported by or linked to external organizations such as credit unions and banks. NGOs have been proactive in promoting such groups among less-educated, low-income women, because such women are the least likely to have access to formal means of saving and borrowing.

Definition of the Nonprofit Sector

Nonprofit researchers are interested in defining the nonprofit sector, delineating its scope, and understanding the factors determining its existence and activities. While definitions vary, it is generally agreed that the nonprofit sector is a set of social entities that are mainly formally organized, privately initiated, self-governing, involved in development issues on a nonprofit basis, and working to mobilize public spirit and altruism to create social and civic benefits for the needy. The term NGO is understood to refer to those autonomous, nonmembership, relatively permanent or institutionalized (but not always voluntary), intermediary organizations, staffed by professionals or the educated elite, which work with grassroots organizations in a supportive capacity. Grassroots organizations on the other hand are issue-based, often ephemeral, membership organizations; they may coalesce around particular goals and interests and then dissipate once their immediate concerns have been addressed. NGOs have become an important and vocal platform for the involvement of civil society in public affairs and may collaborate with grassroots/community-based organizations. There is also a distinction made between northern and southern NGOs, based on the organizations' location of operations. NGOs based in northern developed countries tend to fund programs and activities of NGOs in the southern developing countries. Northern NGOs seek funding from multilateral and government aid agencies and also develop their own financial base through private fund-raising activities. Recently a lot of southern NGOs have also started to aspire to financial independence and do their own private fund-raising activities locally.

NGOs are popular because they demonstrate unique characteristics and capabilities: they are perceived to be flexible, open to innovation, and able to access the poor through work at the grassroots level. NGOs play three main roles: service delivery, advocacy on behalf of the poor, and empowerment.

Functions of the Sector

Service Delivery

NGOs have come to play an increasingly important role in the formulation and implementation of policy, becoming key actors in the political economy of development. They have increasingly collaborated with governments and aid agencies in the developing world as the belief has grown that NGOs can offer an alternative model of development and play a key role in processes of democratization and decentralization of policies.

NGOs are seen as more administratively flexible, closer to the poor, innovative in problem solving, and more cost effective than corresponding state partners. Donor pressure toward structural reform and privatization in the Southern Hemisphere in the 1990s underlies the increased interest in NGOs as 'service deliverers,' part of a wider and explicit objective to facilitate productive NGO–state partnerships. There is a realization among donor countries in the global north that aid is becoming ever more complex as new instruments and players emerge and as criticisms over the effectiveness of aid increase. Private financial flows from corporate sector organizations in northern developed countries have increased rapidly in the wake of increased liberalization. These increases are in part the result of enhanced understanding of corporate social responsibilities and of the creation of organizations such as the Bill Gates Foundation, the Ford Foundation, and the Aga Khan Foundation. These developments have also led to an expansion in partnerships between northern NGOs and southern NGOs and have changed attitudes toward development interventions in the North. A view took hold that merely transferring resources in the form of tools or funds was not an adequate response to alleviating poverty, which was rooted in deeper structural problems. Indeed such transfers could just preserve the situation by creating financial dependency. Greater collaboration between corporations and NGOs can also create inherent risks of cooptation for the weaker partner, typically the nonprofit organization involved (Baur et al., 2012).

Former UN Secretary General Kofi Annan wrote in favor of international humanitarian intervention, arguing that the international community has a 'right to protect' citizens of the world against ethnic cleansing, genocide, and crimes against humanity. Northern NGOs such as Red Cross and Oxfam have a humanitarian function and respond to emergencies, providing short-term relief and long-term rehabilitation to victims of war and of natural or man-made disasters. These organizations raise money in the North from the general public, the private sector, and governments to pay for their work; they share funds as much as possible with their southern counterparts, help in building the capacity of southern NGOs, educate their own constituencies in the North about the underlying causes of poverty, and draw people into active lobbying and campaigning for change. Southern NGOs have the basic responsibility among NGOs for leading the development process in developing countries and the expertise to do so.

Policy Advocacy

The other frequent role for NGOs is policy advocacy, seeking social change by influencing attitudes, policy (see Pollard and Court, 2008), and practice; seeking to reform state services on the basis of NGO experiences and to lobby directly for the policy changes and reform. This is involvement in participatory, public-interest politics; NGOs engaging in such activity realize the increasing importance of information, which they gather through their own experience of working at the

grassroots level. They use the power of ideas and information to promote positive change in the wider structures of government and the official aid community. These NGOs often play a catalytic or seeding role by demonstrating the efficacy of a new idea, publicizing it, perhaps persuading those with access to greater power and budgets to take notice, and then encouraging the diffusion and adoption of the idea. In recent decades, though, NGOs have devoted their energies to advocacy campaigns. Drawing on new opportunities afforded by growth in their numbers and size and in the resources available to them, and facilitated by the revolution in communications technologies, NGOs have globalized, seeking to maximize their impact on global policy processes by working through transnational networks. In terms of environmental issues and sustainable development, the Earth Summit in Rio in 1992 was the first to show the power of international NGOs, when about 2400 representatives of NGOs came to play a central role in deliberations and highlighted that NGO transnational networking is now quite extensive.

The Jubilee 2000 Campaign was the first global campaign through which development NGOs united over a single issue – debt relief for the world's most heavily indebted nations. Jubilee 2000 mobilized over 24 million people from over 60 nations to sign a petition (Mayo, 2005: 174), drawing supporters of all ages and occupations from faith-based and secular organizations, trade unions, and businesses. With 110 member organizations, within 4 years of its launch in 1997, "Jubilee 2000's campaign for the remission of unpayable Third World debt made a remarkable impact, raising the issue's profile internationally as well as locally" (Mayo, 2005: 172). After a concerted lobbying campaign, in 1999 at the Cologne G8 Summit, world leaders agreed to cancel $100 billion of debts owed by the poorest nations (Bedell, 2005: 19). The campaign is credited with having contributed to poverty alleviation, enabling diversion of resources from debt repayment to increased spending on health care, housing provision, and education. Similar success is attributed to the 'Make Poverty History' campaign in London in 2005.

In 1995, Oxfam International established its Washington Advocacy Office to coordinate the development of joint policy and strategies for the nationally based Oxfams. Its location in Washington, DC, facilitated direct access to Washington-based multilateral agencies, the World Bank, the International Monetary Fund, and the United Nations, headquartered in New York. By 2012, Oxfam International supported advocacy and campaigning staff in Washington, DC, Geneva, New York, Brussels, Brasilia, and Addis Ababa (Oxfam International, 2012).

In the United Kingdom, Bond, the membership body for NGOs working in international development, established in 1993, had 400 members by October 2014 (Bond, 2014). Listed first among its activities, Bond "facilitates collective action by its members and wider UK civil society to influence the policies and practice of governments and institutions at UK, European and international levels" (Bond, 2012).

This trend has also reflected northern NGOs' reaction to calls from their southern partners to increase their engagement in advocacy. Because northern NGOs' greater access to power and resources enabled them to engage with global institutions and influence their policies, southern NGOs consistently called for northern NGOs to lobby and campaign about the global crises of poverty and environmental degradation. Concurrently, an evolving emphasis in development practice on the importance of empowering local communities to participate in all stages of the development process resulted in recognition that growing numbers of southern NGOs were best placed to initiate and manage development work in local communities. Northern NGOs thus responded by looking for new ways to contribute to poverty alleviation.

In recent decades, northern NGOs' financial commitment to advocacy has grown; this growth is evident in the budgets, staff time, and the departments dedicated to research and lobbying. In 1996, just 4.1% of total expenditure by international NGOs was dedicated to advocacy (Anderson, 2007). Anderson tracked the financial commitment of 14 international NGOs to policy research, lobbying, and public campaigning and found that between 1996 and 2005 this commitment increased dramatically. Only three increased their resource allocation to advocacy by less than 100%; over half increased the financial and human resources allocated to advocacy by three or six times (Anderson, 2007). Thus, in recent decades, NGOs have given greater priority to advocacy, prompted by the success of earlier campaigns.

Empowerment

The roles of service delivery and policy advocator include the process of empowerment. Some NGOs naturally progress from filling a gap in service delivery to recognizing the need to look outward to the wider context in which the need arises and find themselves drawn, possibly through involvement in NGO networks (Bebbington, 2003), into national or global policy advocacy (e.g., cancellation of debt of heavily in debt nations, placing it on the agenda of the G8 summit in Gleneagles in July 2005 – see Brown et al., 2012). This type of 'bottom-up democracy' has been successful in many instances in which it might eventually lead to 'top-down political change.'

NGOs have become key actors in a process of transformative development. They can effect norm changes that lead to regime change or restructuring of world politics. They do this (especially northern NGOs) through the communicative power of information, lobbying, research, campaigning, or media work, acting on the basis of their moral authority (for example, in the area of human rights (see Van Tuijl, 1999), free trade, debt relief, child labor, or fair trade). NGOs create alliances and networks to place pressure on the state (DeMars, 2005). Recently, NGOs have been drawn into networks of growing complexity. This has led for some to call for "power to be put back into empowerment" (Batliwala, 2007a), not only recognizing power as a vital component of the concept of empowerment, but also appreciating that power structures can hinder or affect an individual or group's ability to exercise power. Batliwala (2007a) suggests that notions of empowerment can be seen in the Protestant Reformation in Europe and, as a concept, can be traced through Quakerism, Jeffersonian democracy, early capitalism, and the black power movement. She also argues that empowerment as an idea is evident in the Veerashaiva movement in twelfth- and thirteenth-century Karnataka, India, which agitated against "caste and gender oppression, (calling) for the redistribution of power and access to spiritual knowledge through the destruction of these forms of social stratification" (2007a: 558). In

1970, Paulo Freire highlighted the importance of developing a critical consciousness, or to use his term 'conscientization' as a first step in processes of empowerment. He believed that everyone has the capability to participate in raising his or her own consciousness. This has been taken on by many in the NGO sector in various aspects of their work and has become part of many movements (e.g., feminism), and the importance of collective action has been adopted by those who understand the crucial elements of empowerment as power from *within* and power *with*.

Challenges Facing the Nonprofit Sector

Among the challenges facing the nonprofit sector are the following.

Sustainability and Long-Term Impact of NGO Operations

An important role for NGOs in the last few decades has been in mitigating the adverse costs of structural adjustment and promoting donor reform packages in offering insurance against a political backlash against harsh adjustment regimes. Such a role raises important questions. Patterns of service delivery through the voluntary sector may lack compatibility and coordination. Insofar as such efforts rely on government funding or private donations, the ultimate sustainability of NGOs is questioned. Will NGOs be able to fund their own operations and activities in the future? Will NGO funding create dependency? At a deeper level, there are worries about the long-term impact of NGO service provision on the sustainability of national health and education systems (rather than individual programs) and about access to quality services for all. NGOs also constantly face the challenge of the need to adopt approaches that 'best fit' in the context of a particular country, region, or community, and existing institutions rather than importing 'best practices,' which may not apply in certain local contexts (Dodman and Mitlin, 2013).

Accountability, Evaluation, and Performance

Funders generally require reporting and assessment; such information is not necessarily publicly available. Instead of relying on financial data or solely quantitative measures, qualitative evaluations might be more useful. Such evaluations could examine organizations' transparency, governance, and program effectiveness as well as the feedback mechanisms designed for donors and beneficiaries (Lowell et al., 2005). More generally, the popular discourse of nonprofit evaluation should move away from financial notions of organizational effectiveness and instead move toward assessing the impacts of programs that are implemented and focus on the beneficiaries who are the recipients of programs.

Legitimacy

As nonstate actors with considerable influence over governance in many areas, NGOs have generated concerns about the extent to which they represent the views of the public and the extent to which they allow the public to hold them to account. In recent decades NGOs have increased the number and range of their activities to a level where they have become increasingly dependent on a limited number of funders/donors (Edwards and Hulme, 1995). Consequently competition has increased for funding, as have the expectations of the donors themselves. This runs the risk of donors adding conditions that can threaten the independence of NGOs, and an overdependence on government aid has the potential to dilute "the willingness of NGOs to speak out on issues which are unpopular with governments" (Edwards and Hulme, 1996). In these situations NGOs are being held accountable by their donors, which can erode rather than enhance their legitimacy, a difficult challenge to overcome. Some commentators have also argued that changes in the sources of NGO funding have ultimately altered their functions.

The expansion of the nonprofit sector has also been accused of damaging the public sector in many developing countries. The mismanagement of NGOs has resulted in the breakdown of public health care systems in many Asian countries, such as India, Thailand, and Cambodia. Instead of promoting equity and alleviating poverty, NGOs have been under scrutiny for contributing to socioeconomic inequality and disempowering the services in the public sector of developing countries.

Administrative Cost

In recent years concerns have been raised regarding the level of administrative costs (e.g., office expenses, salaries) incurred by NGOs in managing projects and programs. The sector as a whole has developed various codes of ethics; for example, the World Bank typically allows 37%. High administrative costs can generate criticism that NGOs are being run simply to benefit the people working for them. Studies by the Urban Institute and the Center for Social Innovation at Stanford University have shown how rating agencies create incentives for nonprofits to lower and hide overhead costs, which may actually reduce organizational effectiveness by starving organizations of the infrastructure they need to deliver services effectively (Lowell et al., 2005).

Conclusion

Debates about the most appropriate forms of development intervention have persisted among development practitioners and theorists. Theorizing about development in the 1980s, notably by radical development theorists, contributed to understandings that 'underdevelopment' was a condition maintained by inequitable global structures, such as entrenched unfair terms of trade, poor commodity prices, oppressive debt obligations, and inequitable distribution of resources among different social groups and nations. Simultaneously, NGOs grappled with the uncertainties of development practice as they endeavored to find the most effective means to improve quality of life for those suffering the ravages of poverty and disadvantage. One common criticism of NGOs was that their focus on local development and empowerment meant they failed to consider the wider structural factors that perpetuated poverty (Edwards and Hulme, 1992). Decades of local development efforts also led to the realization that project work in communities is insufficient to bring about broader changes to address the ongoing causes of poverty. Responding to this insight and to

the new theoretical understandings, NGOs sought to tackle causal factors by increasing their commitment to advocacy, with the aim of maximizing the impacts and cost-effectiveness of their work.

Working collaboratively to broaden their impact, NGOs were drawn into networks of growing complexity. The primary impetus was growing awareness of the power of public action through experience of its success. Although arguably "little progress at the level of ideology and global systems" (Nyamagasira, 2002: 8) results from NGO action, through uniting in alliances NGOs "materially contributed to policy changes by Northern and Southern governments" (Anderson, 2002: 84). These included the success of campaigns relating to baby milk marketing codes, drafting of an international essential drugs lists, trade liberalization relating to clothing manufacture in southern nations, action against global warming and rain forest destruction, debt relief to African nations, fair trade pricing, and the imposition of sanctions to combat apartheid (Anderson, 2002).

Nonsampling Errors

Elizabeth A Stasny, Ohio State University, Columbus, OH, USA

This article is reproduced from the previous edition, volume 16, pp. 10691–10696, © 2001, Elsevier Ltd.

Abstract

Data from sample surveys are subject to both sampling and nonsampling errors. The latter include errors from the sampling frame, the questionnaire, the interviewer, and the respondent. The article defines and sets out ways to deal with various errors. Sampling frame errors may be overcome by random digit dialing for telephone surveys or dual-frame sampling. Response error (incorrect answers) may be dealt with by randomized response techniques, while nonresponse errors may be minimized by weight adjustments and imputation methods. Panel rotation and survey mode errors are also briefly considered.

Data from sample surveys are subject to two types of errors: sampling and nonsampling errors. Sampling errors result from the fact that we only have information from a portion of the population of interest rather than from the whole population. Nonsampling errors include errors from all other sources: the sampling frame, the questionnaire, the interviewer, and the respondent. Data from both censuses and surveys may suffer from nonsampling errors, while only survey data are subject to sampling error.

Statisticians have traditionally been most concerned with controlling and measuring sampling errors, perhaps because they are easier to handle. Sampling errors are controlled by choice of the survey design; the size of the sampling error can be estimated using the survey data themselves. The emphasis of most classical survey sampling books such as Cochran (1977) and Kish (1965) is on measuring sampling error and designing surveys to reduce that error.

More recently, authors such as Lessler and Kalsbeek (1992) and Biemer et al. (1991) have focused on issues related to nonsampling error. Such errors must typically be assessed using information outside of the survey (or census) data or using a statistical model. As is noted by Mosteller (1978), sampling errors typically contribute to the variance of an estimate from survey data (and do not exist for census data), while nonsampling errors can contribute to both variance and bias of an estimate. In collecting survey or census data we try to control, reduce, or avoid nonsampling errors as much as possible because their size and effect on estimates are very hard to assess.

Frame errors, response errors, nonresponse errors, and other sources of errors are all nonsampling errors. The following describes these nonsampling errors and methods for dealing with them.

Frame Error

Definition of Frame Error

The sampling frame is the list from which units are drawn for the sample. The 'list' may be an actual listing of units, as in a phone book from which phone numbers will be sampled, or some other description of the population, such as a map from which areas will be sampled. Frame error results when the sampling frame is not an accurate and complete representation of the population of interest.

Frame errors arise from erroneous inclusions, erroneous exclusions, and multiple inclusions. Erroneous inclusions occur if the frame includes units not in the population of interest so that invalid units have a chance of being included in the sample. Erroneous exclusions occur when members of the population of interest are missing from the list so that they have no chance of being sampled. Multiple inclusions occur if some population members appear multiple times on the list so that they have a higher chance of being sampled.

For an easy example of these types of frame errors, consider sampling households within a city using the telephone white pages as the sampling frame. Some numbers listed in the phone book are no longer working numbers because the people in the household that had the number have moved out of the city; these are erroneous inclusions. Some households choose to have their phone numbers unlisted; these are erroneous exclusions. Some households have multiple listings in the phone book because they have additional telephone lines for a computer modem or for a fax machine or for the children; these are the multiple inclusions.

Frame error is a problem because a sample drawn from such a frame may not represent the population of interest, from which you think you are sampling, and some units may have a higher probability of being included in the sample than most units. These errors may result in sample estimates that are biased for the population quantity being estimated. For example, if wealthier households are more likely to have multiple phone lines, then those households are more likely to be included in the sample. This could lead to estimates of, say, amount spent on entertainment that are biased high.

Dealing with Frame Error

As is the case with all nonsampling errors, the best way to control frame error is to avoid or minimize it. Methods for doing this depend on the type of sampling frame that you are using. We will discuss two commonly used methods in this section: random digit dialing (RDD) and dual-frame sampling.

Random Digit Dialing

For telephone surveys of individuals in households, RDD is often used to avoid problems associated with using a telephone directory as the sampling frame. To create the sampling frame for an RDD sample, one must first list all working area codes in

the area to be sampled. Within each area code, one must list all working exchanges. If all possible four-digit numbers that could complete the phone number were used to make up the sampling frame of phone numbers, there would be numerous nonworking numbers and business numbers included. Because calling such numbers to determine that they are not valid household numbers is time-consuming and expensive, other methods may be used to reduce the number of invalid phone numbers in the frame. One method takes advantage of the fact that phone numbers are typically given out in banks of 100. Thus, the frame is taken to be the list of area codes with their exchanges followed by all possible first two digits of the remainder of the number. These eight-digit numbers are clusters of 100 possible phone numbers. A random sample of these clusters is taken and then two two-digit numbers are chosen at random to give two potential phone numbers within each cluster. The two sampled numbers within each cluster are called. If both are nonworking numbers or business numbers, then the cluster is discarded because it is likely that the remaining possible numbers in that cluster are also invalid numbers.

Once a valid household is reached, one still must determine who is to be interviewed within the household. If a single adult respondent is to be selected, a method proposed by Kish (1949) may be used to randomly select that adult. Because Kish's method involves creating a roster of all individuals within the household, which can be time-consuming and may be considered intrusive by potential respondents, other methods such as asking for the person who had the last birthday may be used as a quick method of selecting an individual within a household (see Lavrakas (1993: pp. 111–13) for a description of the last birthday and next birthday methods).

There are, of course, some problems with RDD samples. For example, persons who live in households with no telephone are not included in the sampling frame. Households with multiple telephone lines have a higher probability of being selected for the sample. One must account for this by asking respondents how many phone lines they have that are used for voice correspondence and use this information to adjust the selection probability for that household. If one is searching for a very specific population, such as households with disabled persons or early voters, then many of the households reached by telephone will be ineligible for the survey and must be screened out of the sample. The higher the proportion of households that must be screened out because of ineligibility, the higher the final cost of the survey will be.

Dual-Frame Sampling

In many sampling settings there are multiple lists or sources that can be used to develop a sampling frame. For example, the US Department of Agriculture uses lists of farms and area maps to select samples for their crop surveys. Samples from the lists of farms are easier to obtain but miss some farms; the area samples are difficult to handle but encompass all possible farms (see Bosecker and Ford, 1976 for details). A survey of patrons of the arts may use lists of season ticket holders to the symphony, ballet, and opera along with lists of persons who have made contributions to art museums. The challenge when multiple lists are used is to unduplicate the lists or to determine how many ways a person could be selected for the sample. Unduplicating lists to create a single sampling frame is complicated by problems such as incorrect spellings of names, use of complete first names versus initials, and spouses who may donate together or individually. Procedures for unduplicating lists must search for possible matches as well as for exact matches. These possible matches may need to be resolved by hand. Alternately, sampling may be done from the multiple lists and respondents may be asking how many of the lists they should appear on. This allows one to determine the probability that an individual was selected for the sample.

Response Error

Definition of Response Error

Response error occurs when a respondent intentionally or unintentionally gives an answer to a survey question that is not correct. An intentional response error occurs when the respondent purposely gives an incorrect answer, for example, to a question that asks for sensitive information about illegal activities (drug use, cheating on taxes), for personal information on sensitive topics (being a victim of rape), or about behavior that may not be perceived as socially acceptable (not voting, owning a gun). The respondent may give an intentionally incorrect answer for self-protection if he or she is concerned that the survey responses will not be held confidential and may be used against him or her. Or the respondent may not wish to appear in a bad light to the interviewer and may give the more socially acceptable answer.

Unintentional response errors can occur if questions are poorly worded and the respondent does not understand the question or terms in the question. The order in which questions and response choices are presented to a respondent can influence the responses that are given. In addition, response errors can occur if the respondent does not take time to think about a question that asks for an opinion and instead takes the easy option of agreeing with the statement or choosing the answer that is easiest to recall (called satisficing). (See Krosnick and Alwin (1987) for details on response-order effects and satisficing.)

Avoiding Response Error

Carefully designed and worded questionnaires, and, for in-person or telephone surveys, well-trained interviewers are the best tools for avoiding response errors (*see* Sample Surveys: Cognitive Aspects of Survey Design). Questionnaires must be pilot tested to ensure that respondents understand questions and that all possible responses are allowed for on closed-form questions.

Randomized Response Techniques for Sensitive Questions

Randomized response methods have been proposed by a number of researchers (see, for example, Warner, 1965; Nathan, 1988) to avoid the problem of having respondents intentionally give an incorrect answer to a question. The idea is to protect the respondent by ensuring that the interviewer is unaware of which question the respondent is answering.

There are several versions of the randomized response technique. In one, the respondent randomly selects one of two types of cards containing opposite versions of the question. For example,

Version A:
I have used cocaine at least once. YES/NO
Version B:
I have never used cocaine. YES/NO

Whichever the respondent answers, yes or no, the interviewer does not know whether the respondent has used cocaine or not. The data from such responses, however, can be used to estimate the proportion of the population that has used cocaine as long as there are unequal numbers of Version A and Version B cards.

Let p = population proportion of interest (here the proportion that has used cocaine). Let $\theta \neq 1/2$ be the proportion of Version A cards. Suppose that Y of the n respondents answered 'yes' to whichever question they were asked. One can use conditional probability arguments to show that an unbiased estimate of p, assuming simple random sampling and ignoring the finite population correction factor, is

$$\tilde{p} = (\theta - Y/n)/(2\theta - 1)$$

The variance of this estimator is

$$Var(\tilde{p}) = p(1-p)/n + \theta(1-\theta)/n(2\theta - 1)^2$$

which is larger than that obtained by asking the question directly, $p(1 - p)/n$, because we have introduced extra variability by asking a randomly chosen question. Notice that the variance will decrease as θ gets closer to 0 or 1, so that most of the cards are of one type (Version A or Version B). Thus, from a mathematical perspective, we prefer θ far from 1/2. Respondents, however, prefer θ close to 1/2, so that they feel confident that the interviewer does not know what question is being answered. The trade-off is an increase in variance in order to ensure that the respondent will provide a true, unbiased response.

In practice, randomized response techniques are not as successful as one would hope. The explanation of the technique may confuse the respondent, or the respondent may not really believe that the interviewer does not know what question is being answered. Thus, such techniques must be used with great care.

Nonresponse Error

Definition of Nonresponse Error

Almost every data collection endeavor results in missing data or nonresponse. In telephone or in-person surveys and censuses, for example, some sampled individuals cannot be located during the interview period, some are ill or unable to communicate with the interviewer, and some refuse to respond to the survey. The best that one can hope for when there is nonresponse is that the missing data are like a random sample of the units selected for the survey. If this is the case then the data are said to be missing completely at random and the effect on estimates is that they are more variable since they are based on a smaller sample size than planned. More often, however, those who do not respond to the survey differ from those who do respond on at least some survey variables of interest. In these cases the data are said to be missing at random if the missingness can be explained by other variables that are observed; nonresponse is nonignorable if the missingness depends on the value that is not observed (see Little and Rubin (1987) for a more complete discussion of types of missingness). For example, people who are not at home to respond to a telephone survey in the evening may watch less television than those who are at home. In this case, estimates of average hours of television viewing per week based only on data from respondents will be biased low. (Note that the above example also illustrates why it is not appropriate to replace nonresponding units in your sample with other units from the population: if there are differences between responders and nonresponders, choosing additional responders only repeats the bias on a larger scale.)

Nonresponse is a particular problem in longitudinal or multiple-wave surveys and studies where sampled individuals may drop out of the study after several interviews. If the reason for dropping out is related to the variables of interest, then nonresponse bias is introduced. For example, individuals in housing units sampled for the US National Crime Victimization Survey are interviewed seven times over 3.5 years. Individuals who move out of sampled housing units are not followed. If individuals who experience crime are more likely to move, perhaps to a safer neighborhood, then estimates of victimization rates will be biased low (see Lohr (1999) for a description of the National Crime Victimization Survey). A similar problem occurs in longitudinal medical studies if, for example, patients given the placebo see no change in their condition and thus are more likely to drop out of the study than patients receiving a treatment.

There are two types of nonresponse in surveys and censuses: unit nonresponse and item nonresponse. If no survey information is collected from a sampled unit, this is termed unit nonresponse; if a sampled unit responds to some, but not all, survey questions, this is termed item nonresponse. There are different methods for dealing with unit and item nonresponse.

Dealing with Nonresponse Error

The best way to deal with nonresponse error is to try to avoid it. Thus, good survey organizations use repeated callbacks on telephone and in-person surveys and reminder postcards or multiple mailings on mailed surveys to try to reach sampled individuals. Introductory letters or statements at the beginning of questionnaires should describe the purpose of the survey, provide information on who is funding and conducting the survey, stress the importance of the person's responses to the survey, and assure the respondent that all survey responses will be kept confidential. Some surveys provide a payment or gift to respondents or draw for prizes from among the respondents to encourage response.

In spite of the best efforts to encourage response, most surveys suffer from nonresponse. A researcher thus has the responsibility, at a minimum, to report the nonresponse rate for the survey along with any results from the survey. There

can be many definitions of the response rate for a survey, depending on whether one counts all units originally sampled or only those that led to eligible respondents or only those that resulted in some contact with a respondent, and so forth. See the American Association for Public Opinion Research (1998) for standard definitions of response rates.

The first step in dealing with nonresponse is to conduct exploratory data analysis on the survey data. For unit nonresponse, after determining the overall nonresponse rate one should then look at response rates by other variables that are available for both responding and nonresponding units. For example, in a mailed survey of a larger city, one could look at response rates by zip code. If there are big differences in response rates for various areas of the city, say that there are higher response rates from the more affluent areas, then survey estimates for variables that are related to affluence, such as support of the arts, are likely to be biased. In a survey of university alumni, one can compare respondents and nonrespondents on any of the variables available in the university alumni database such as GPA. If, for example, those with higher GPAs responded more often than those with lower GPAs, then survey estimates on variables related to GPA, say starting salary in the first job after graduation, are likely to be biased. If one does not find differences such as those suggested above, then at least one knows that there are not differences on the variables that could be explored. This does not, however, insure that there are no differences between respondents and nonrespondents on the survey variables of interest.

For item nonresponse, one should start by determining how much nonresponse there is for each variable with some missingness. For key study variables, one should look at summaries of other variables according to whether or not the key variable is missing. For example, if income is a key variable and subject to nonresponse, one could look at average age, average years in job, proportion married, proportion with high school diploma or less, and so forth for respondents who reported their income and those who did not. Obvious differences between the two groups on the other variables suggest that there are likely to be differences between the respondents and the nonrespondents on the income variable. It also suggests that the other variables might be useful in determining an adjustment for the nonrespondents, as described below.

Weight Adjustments

The sample-based weights assigned to cases in a sample survey can be interpreted as the number of people in the population of interest that the individual in the sample represents. The initial weight is usually the inverse of the selection probably for each sampled unit. One commonly used method to adjust for unit nonresponse in a sample is to increase the weights of respondents to account for nonrespondents. This adjustment is usually done within weight-adjustment cells within which it must be assumed that nonrespondents are 'just like' nonrespondents on variables of interest. That is, within weight-adjustment cells, the nonrespondents can be thought of as a random sample of the sampled units in that cell.

As a simple example, suppose you have a simple random sample of $n = 100$ individuals: 50 men, of whom 30 respond, and 50 women, of whom 40 reply. (Since we are assuming that a simple random sample of individuals was selected, all individuals in the sample will have equal selection probabilities and thus equal initial weights.) If you believe that within gender the nonrespondents are 'just like' the respondents (that is, the nonrespondents can be thought of as a random sample of those originally sampled) on survey variables of interest, then you may decide to use male/female as the weight-adjustment cells. The 30 responding males would represent themselves and the 20 nonresponding males. Thus, the original weights of the males must be multiplied by 50/30. Similarly, the original weights of the women would be multiplied by 50/40 to account for the nonresponding women.

In practice, there are usually more than the two nonresponse adjustment cells described in the simple example here. Little and Rubin (1987) describe methods for creating the nonresponse adjustment cells. Brick and Kalton (1996) provide details on weight adjustments for nonresponse.

Imputation Methods

Imputation methods are most often used to deal with item nonresponse. Imputation is defined as replacing a missing value by a plausible value. An advantage of imputation is that it creates a completed data set that can be analyzed using standard statistical methods. A disadvantage is that most subsequent analyses ignore the fact that imputation was done and, therefore, underestimate the variance by ignoring the uncertainty due to the imputation. There are many methods for creating plausible values to impute for a missing value. The better methods make use of information in the available data or in an auxiliary data source to estimate the missing values. The following describes some common methods of imputation. More details and additional methods may be found in Little and Rubin (1987) and Missing Data.

Mean imputation involves replacing a missing value of some variable by the sample mean computed from all individuals who reported a value for that variable. For example, mean income from those who reported income would be imputed for all those who refused to report income. The main disadvantages of mean imputation are that it distorts the distribution of the variable by creating a spike at the mean value, and it distorts relationships and correlations among variables. For example, the relationship between years experience on the job and income is not preserved when mean income is imputed for all those missing income regardless of years of experience. For this reason, mean imputation may be done within imputation cells that are determined by variables thought to be related to the missing values. Thus, years experience may be used to divide respondents into groups, and the mean income within each group is imputed for those missing income in the group. Mean imputation within group still created spikes in the data (at the mean for each group) and distorts the relationships among variables, but these effects should be less than with overall mean imputation.

Regression imputation involves using a regression model fit from complete cases to estimate missing values. For example, complete cases may be used to develop a model for income based on age, education, tenure in job, and other available data. This fitted model would then be used to estimate income when it is missing. Because this method may also create spikes

in the data when there are few possible combinations of the predictor variables used in the regression model, a variation involves adding a random error to the estimated value to be used for imputation.

Cold deck imputation involves using auxiliary data as a source for missing values. For example, data from administrative records might be used to obtain missing survey values, or, in a panel survey, values from a previous interview for the same respondent could be used to replace missing values. Hot deck imputation replaces missing values with values taken from other similar respondents' records in the same data set.

The imputation methods described above all result in underestimation of the variance because the imputed values are treated as 'truth' and subsequent analyses typically ignore the uncertainty in the imputations. Multiple imputation, first developed by Rubin (1987), allows one to account for this uncertainty. In multiple imputation, a stochastic imputation procedure is used to create, say, m imputations for each missing value. These m completed data sets are used in the standard analysis of the data. The variation among estimates from the m analyses is used to estimate the variance due to imputation. It is combined with the usual variance from the standard analyses to provide an overall variance of the estimates. For most larger surveys, m can be fairly modest: $m = 5$ is often adequate. For more details, *see* Multiple Imputation.

Other Sources of Error

There are other sources of nonsampling error that can affect survey data. Errors caused by interviewer bias, panel rotation, survey mode, coding, and data entry are all errors that should be avoided in conducting surveys. We will briefly consider panel rotation and survey mode errors.

Panel rotation error occurs when responses to a survey change depending on the length of time the panel has been included in the survey. Bailar (1975) described the effects of time-in-sample for the US Current Population Survey. In general, the longer a person has been in the sample, the less likely the person is to report being unemployed. A similar effect is found in the US National Crime Victimization Survey; persons in the survey for a longer time are less likely to report a victimization. Possible explanations for this phenomenon include that respondents learn to answer the survey so as to minimize the amount of time it takes to complete the survey or that differential dropout leads to a biased sample over time.

Survey modes include in-person, telephone, self-administered paper-and-pencil questionnaires, and, most recently, self-administered Web questionnaires. The same questions asked using different survey modes can elicit different responses (*see* Sample Surveys: Cognitive Aspects of Survey Design). For example, respondents are more concerned about their self-images in personal interviews than on paper-and-pencil surveys. Thus, they may be more likely to report personal problems on a self-administered questionnaire than in a face-to-face interview. On the other hand, security and confidentiality concerns may make respondents less likely to respond truthfully to surveys on the Web. The accuracy of responses to Web surveys is an area of ongoing research.

Additional information on these other sources of nonsampling error can be found in references such as Groves (1989) and Biemer et al. (1991). An excellent example of a survey for which all sources of error, both sampling and nonsampling, are explored in detail is the US Current Population Survey (see US Department of Commerce, 2000).

Nonstandard Reasoning

Johan van Benthem, University of Amsterdam, Amsterdam, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, nonstandard reasoning refers to the proliferation of reasoning styles investigated in modern logic beyond its traditional agenda. After a brief statement of standard logical approaches to consequence, we describe motivations for new systems. These include not only inference patterns with special vocabulary from mathematics, philosophy, and linguistics but also new styles of reasoning coming from computer science and artificial intelligence. The resulting landscape is diverse, but we discuss unifying themes such as structural rules, preferences, resources, information, and architecture of logical systems. Many of these reflect recent cognitive trends in modern logic putting 'social dynamics' at center stage: reasoning about one's own information and that of others, information update, acts of communication, processes of inquiry, and games.

The Emergence of Nonstandard Logics

Logic since antiquity has been concerned with 'the laws of thought,' supposedly unique and immutable principles of valid reasoning from premises to conclusions. Gradually, over the twentieth century, this monolithic view has changed to a pluralist one where logic tries to chart the different human reasoning styles and their matching logical systems. With the emergence of information, computation, and cognition as central scientific themes in recent decades, new items have kept appearing on this broader agenda. The resulting systems are often called 'nonstandard logics,' different from the established regime, but this label is relative. The background to current broader studies of reasoning are still the major approaches to valid inference in standard logic (semantic or proof-theoretic) developed by reflecting on philosophical argument and mathematical proof. Over time, however, these approaches have acquired richer vocabularies and additional notions of inference, whose motivation comes from philosophy, mathematics, linguistics, and many other disciplines. In particular, nonstandard logics often originate in computer science and artificial intelligence when thinking about key patterns in action, problem solving, or planning: arguably human core skills where reasoning may in fact have developed first in our evolutionary history. The resulting landscape of systems is diverse, but there are unifying themes such as structural rules of inference, information structure, preferences, resources, knowledge, or architectures for combining systems. These themes also reflect what might be called more realistic cognitive trends in modern logic: reasoning about one's own information and that of others, processes for information update and inquiry, communicative acts such as questions and answers, games and rational strategic interaction, and in all these, the use of heterogeneous information from symbolic, graphic, and other sources. In other words, the somewhat negative term 'nonstandard' will be understood in this article as natural agenda extensions of logic that go beyond the traditional core concerns.

Standard Logic: Valid Consequence, Proof Calculi, Completeness

The term 'standard logic' is mostly used to refer to the achievements of the renaissance of formal logic, starting with Boole, Frege, and Peirce in the nineteenth century, and culminating in the work of Gödel, Tarski, Turing, and others in the 1930s. The resulting core of the field consists of propositional logic (codifying reasoning about classifying situations using sentence combinations with the key operations 'not,' 'and,' and 'or') and predicate logic of quantifiers ('for all' and 'there exists') expressing statements about the internal structure of complex domains with objects and predicates. Together, these systems can describe a good deal of mathematical reasoning, and even quite a few core patterns in ordinary reasoning. Not surprisingly then, they have long been the standard core of most textbook presentations of modern logic. The two systems share what seems to be the most widely accepted semantic notion of valid consequence (due to Bolzano and Tarski) requiring 'transmission of truth' from premises P to a conclusion C:

Each situation in which all the premises P are true also makes the conclusion C true.

To describe and produce valid inferences, one can sometimes use simple mechanical methods, such as the truth tables of propositional logic. While truth tables are simple, and quite suggestive in assimilating reasoning to computation – a perennial theme in logic – they may promise more than can be delivered for logic in general. More general, and at the same time more relevant to capturing the undeniably stepwise structure of actual reasoning, are proof-theoretic approaches, deriving conclusions C from premises P via a system of rules:

Conclusion C follows from P if it can be derived by legitimate proof steps.

Simple steps staying within the reach of human understanding (not too easy, not too hard) are evident not only in mathematical proof but also in common sense reasoning. Proof systems of various sorts have turned out to have an additional benefit: they drive a wide variety of mechanized reasoning systems in artificial intelligence and computational logic.

In addition to system building, logic is also about system theory. Perhaps the first significant insight into logical systems

per se concerns the harmony between the preceding two perspectives. The semantic approach to valid consequence based on truth and the syntactic one based on proof coincide for quantificational logic: this is the content of Gödel's celebrated completeness theorem, which has spawned many similar results for other kinds of reasoning. Another key result is Gödel's even more famous 'incompleteness theorem' showing that formalized mathematical theories going beyond pure logic by adding arithmetical notions are nonaxiomatizable. One of the many consequences of the latter result is Church's theorem saying that no mechanical algorithm can decide validity in quantificational logic. Both positive and negative results have fueled progress in logic. For instance, one major source of variety in logical theories of inference is the search for decidable systems that escape Church's result by judiciously restricting the expressive power of the language of quantification.

Extending the Vocabulary: From Mathematics to Natural Language

Logical systems use 'logical forms' with fixed operators for key notions (Booleans, quantifiers), plus variable parts for expressions that can be interpreted freely (a typical valid form is 'from premises *A*-or-*B*, and not-*A*, infer conclusion *B*'). Propositional and predicate logic have been successful in analyzing mathematical proof, but gradually extensions had to be made to deal with the kind of argument found in philosophy, linguistics, and in the latter part of the twentieth century, computer science and cognitive science. For example, logical semantics of natural language deals with the much richer repertoire that we have for stating and communicating what the world is like according to us. This repertoire includes generalized quantifiers ('almost all,' 'most,' 'many,' and 'few') beyond the standard logical notions of 'all' and 'some,' plus a wide range of so-called modal expressions for our natural daily reasoning involving possibility, time, conditionality, obligation, knowledge, belief, action, etc. – often for both single and multiple agents. The extra vocabulary taken on board here may be considered 'nonstandard,' and determining the additional valid inferences supported by it may be subtle – but the canons of defining validity remain the earlier classical ones.

Alternative Views of Validity

There are also genuine deviations from the classical notion of valid consequence. A recurrent historical example is the view that conclusions only follow validly from consistent premises. Then, nothing follows from a contradiction *A*-and-not-*A*, while on the 'standard' account, everything does. However, this is just one of many hotspots. Alternative views of reasoning may also arise from studying the common vocabulary in human practice that often goes beyond the usual sentence connectives and quantifiers. Alternatives may also have conceptual motivations in philosophy and science.

Deviations in Natural Language, Cognition, and Philosophy

The idea that 'natural reasoning' in our ordinary language differs from standard logical calculi is a recurrent theme in the twentieth century. One hotspot for variations is the crucial logical notion of implication, represented by several expressions in natural language, with 'if…then…' as a ubiquitous example. It seems clear that natural implication does not behave like the truth-functional Boolean conditional – as shown by the 'paradoxes of material implication.' This has led to many deviant calculi not only for 'modal' or 'relevant' implication but also for counterfactual conditionals stating what would have been the case if certain things that are true now had not been the case. These are not just small variations. For instance, counterfactual reasoning keeps much of our thinking about what we do in the actual world 'in place,' and it represents a typical human skill. Some of these phenomena are also put into focus in cognitive psychology, where actual human reasoning behavior appears to be much richer than the repertoire that the standard logical canon has catered for. Finally, in addition to these empirical sources of diversity, there is also the influence of philosophical reflection on reasons, evidence, and knowledge or belief based on these. In contemporary epistemology, sophisticated new dynamic accounts of knowledge in terms of tracking the truth over time, or of constructing and maintaining spaces of relevant alternative worlds, suggest interesting new notions of reasoning that lack many of the basic features of classical systems.

Deviations in Scientific Reasoning

Other modulations on valid reasoning arise in the foundations of science. Starting in the heartland of mathematical logic, 'constructivism' in mathematics views proofs as constructions of mental entities, whose properties must be established by computational means. Accordingly, intuitionistic logic accepts only those inferences as valid that have a constructive proof. For instance, intuitionistically, one cannot prove an assertion 'there exists an x such that $F(x)$' without producing an explicit example, while classical logic would also accept an argument through the back door, namely, a refutation of the proposition that no object x has the property F. Intuitionistic logic is generalized in a wide family of constructive 'type theories' whose validities do not coincide with those of classical logical systems. However, logical proof theory continues to produce new perspectives on valid reasoning. A radical example from the 1980s is linear logic, which reinterprets the propositions involved in inference as information pieces or computational 'resources' that can be used only once. Alternative logics have also emerged in physics. Quantum mechanics has inspired quantum logics with failures of Boolean distributivity laws in reasoning about the location or momentum of particles. (Whether this has to be, or whether classical redescription is possible after all is one of the deep issues in the field.) Most of all, reflecting the close analogies between 'reasoning and reckoning' (as Hobbs put it in the seventeenth century when these views emerged), computer science has inspired many new systems of reasoning. Examples are dynamic logics describing the effects of computer programs and of actions generally, logic programming (using proof systems as computation procedures), description logics (well-behaved weak systems for data bases and knowledge representation), and a host of new systems discovered in artificial intelligence when engaging in the study of 'commonsense reasoning.'

The result of all these developments for logic today is a wide range of alternatives to classical systems, developed with equal rigor, but different in their valid principles, general philosophy, and mathematical properties.

Varieties of Inference

That 'natural reasoning' comes in different styles, with possibly different logical features, was already observed by Bolzano in the early nineteenth century. Scientific reasoning employs stricter standards than common sense (although Bolzano felt that philosophical reasoning was the most demanding skill of all), and common sense as encoded in natural language itself has many varieties, that may even be task dependent. The same variety also occurs in artificial intelligence with problem solving or planning (deductive or heuristic), where systems are more 'optimistic' than standard logic, representing a typical human ability of being able to jump to conclusions, a rich inferential power kept in check by our talent for self-correction once our beliefs turn out wrong. Indeed, more generally, reasoning cannot be seen in isolation from other cognitive skills. In the following subsections we give a few examples.

Nonmonotonic Logics

Practical reasoning uses defaults going beyond standard logical conclusions. Thus, we use some default rule ('Dutch trains run on time') in planning our escape home from a futuristic campus unless counterexamples are explicitly indicated, or, in judging our friends in a cold climate, we take an answer 'John, Mary' to the question 'Who were skating?' as conveying not just that John and Mary skated, but that no others did, assuming a maximally informative respondent. Crucially, such additional inferences may have to be withdrawn later, because new relevant information comes in: my train may be carrying soccer fans, the person answering my question may turn out to be a government employee. Reasoning in which a conclusion C may follow from premises P, but no longer from the richer set $P + Q$ is called 'nonmonotonic' – while classical consequence is monotonic: once drawn, conclusions persist. A general pattern behind much nonmonotonic reasoning is 'circumscription,' which, in its most abstract form, assumes that situations come ordered by some binary relation of preference, and then makes C follow from P if C holds in all most preferred situations where P holds. In the escapist example, the most preferred situations (for the time being) are those where trains run according to schedule, while those containing a disturbing factor are less preferred. This idea comes from artificial intelligence and philosophical logic, and it has a very wide sweep. Preferences may reflect genuine preference, but just as well notions of plausibility, utility, relevance, or simplicity, depending on circumstances.

Classical consequence is not in conflict with this view of reasoning. It is still present here as the special case when no models are preferred to others, making all models for the premises most preferred. Still, there is an intuitive difference, which comes to light in a richer picture of what is happening when these different reasoning styles are deployed. Classical reasoning is safe, and thus, it may be associated with knowledge, and ways of unpacking it. By contrast, nonmonotonic reasoning goes naturally with processes of forming and modifying beliefs, a more volatile attitude than knowledge, but one that is essential to practice. The tandem of inference and belief revision is a crucial practical skill, reflecting two aspects of what it means to 'learn.'

Directions and Purposes in Reasoning

Our presentation so far viewed reasoning as a forward-oriented process of accumulating conclusions from given premises. In addition to this forward mode, there are others. This is already clear with standard uses of classical reasoning for refuting, rather than confirming, opinions or even whole theories. Directions multiply when we consider the rich view of reasoning developed by Peirce around 1900, who distinguished deduction, induction, and abduction. Abduction is the common explanatory reasoning that we engage in when seeking plausible premises to support given observations, or in making sense of what we are told. It provides premises for conclusions, rather than the other way around. In contrast with this, induction looks for plausible generalizations beyond the immediate content of the premises, raising again the issue of learning scenarios, now for general facts going beyond specific observations. These different directions and purposes all matter when analyzing activities such as 'refutation,' 'explanation,' or 'confirmation' in the philosophy of science – but it is also easy to find counterparts for all of them in our daily practice. Moreover, like standard logic, these broader views of reasoning have found their way into computer science. Abduction has been studied in connection with logic programming; varieties of belief revision and induction occur in computational learning theories. In recent years, many of these systems have also been related to cognitive science. For instance, cognitive experiments with conditional reasoning point at nonmonotonic phenomena in actual behavior, and it has even been shown that neural networks in the brain can be represented in terms of nonmonotonic logics with inferences repeated over time.

Reasoning with Uncertainty and Probability

Induction leads naturally to the foundations of uncertainty and probability. Probabilistic reasoning seems a major mode of cognition in its own right. Its standard formalism is definitely not logic, but probability theory. However, starting from Carnap's 'inductive logic' in the 1950s, there is an increasing literature on interfaces between logical and probabilistic reasoning. These include more qualitative styles of probabilistic reasoning in 'fuzzy logic' and 'possibility theory,' and natural hybrids of standard logical and probabilistic systems. Moreover, statistical long-term bulk behavior is coming to the fore as a topic of study, and here 'inference statistics' in terms of percentages of truth and falsity across models, or records of proof attempts, meets logic proper. Finally, qualitative versions of fundamental probabilistic notions such as randomness and independence have been migrating into logic. In particular, new versions of standard predicate logic have attracted attention recently,

allowing for patterns of dependence and independence between variables that go far beyond what has been studied in existing logical systems.

Logical Dynamics: Reasoning as an Activity

Under the influence of ideas from philosophy, computer science, and cognitive science, many logicians have started viewing reasoning as a cognitive process whose dynamics must, and can, be brought out by logical means. This process view of logic is closer to actual argumentation, which is driven by local acts of inferential commitment, while longer term timing and procedural conventions are also crucial to the outcomes.

Dynamic Logics of Information Flow

In this dynamic perspective, reasoning is one of many cognitive tasks that can be studied together. As an early signal of this trend, already the Mohist logicians in ancient China thought that inference, observation, and communication are the three great natural sources of information that should work together. This interplay of different information sources can be observed in the empirical sciences, but just as well in daily practice. Modern logical systems merging inference with a broader information dynamics include dynamic epistemic logics that combine acts of inference, observation, and questions, and axiomatize the laws that describe which new information is generated in each step. The relevant information states can be those of individual agents, but given the social interactive character of much reasoning and related informational activities, these logics often work over multiagent models for different agents having different information.

A further source of diversity here, beyond the dynamic repertoire of actions and events, is the notion of information at work. Inquiry is tied to the usual semantic notion of information as a range of current options that shrinks when new information comes in. However, other powerful intuitions exist, such as the idea that information flows because of correlations or dependencies between different objects or situations that are brought together in reasoning. There is even a third notion. Valid inferences do not shrink a semantic range of options: they rather elucidate a more fine-grained syntactic notion of information, on whose nature there is no consensus at present. The precise sense of information in logic has itself become a topic of discussion and a source of variety.

Dynamic Semantics of Natural Language

Another take on information dynamics is in terms of the meaning of the very expressions used in reasoning. A modern program is dynamic semantics, a view of the linguistic meaning of a proposition as the update of a hearer's information state that is produced by it. Thus, propositions become cognitive procedures, and natural language now resembles a programming language modifying information states of agents.

Dynamic semantics does not stop at reinterpreting vocabulary. It has also been a source of new notions of inference and consequence. One natural dynamic notion of valid consequence from premises P to a conclusion C is the following 'fixed-point' view:

> *In final information states reached by processing the successive premises P, updating with the conclusion C will not have any further effect.*

Dynamic semantics exist for a broad variety of speech acts associated with reasoning and information flow, including questions, answers, suggestions, or commands. Again, multi-agent perspectives come to the fore, as speech acts make little sense in solitude.

Belief Revision, Learning, and Social Information Dynamics

A broader perspective on such cognitive actions arises in belief revision theory, which studies updates adding information to the current state, contractions that remove information, and revisions doing both – doing justice to the 'zigzag character' of much of our reasoning. We have already noted how acts of revision and self-correction form a natural complement to the somewhat risky nature of nonmonotonic reasoning. Forming hypotheses and learning from errors is also crucial to learning theory, which may be considered an extension of information dynamics to a longer term process horizon.

Belief revision and learning may also come in social flavors, since one of the most common causes for belief change is something said by someone else. However, groups of agents also bring their own dynamics, such as the phenomenon of 'belief merge' between different groups. Such phenomena have been studied for computational agents, and recently also in social philosophy and social choice theory, since votes are only stages in some larger setting of communication and deliberation, i.e., social reasoning.

Logic and Games

Perhaps the most 'activist' perspective on reasoning is one borrowing some major concepts from game theory. Many basic logical notions can be cast in the form of games. Argumentation is a key example, but the same is true for evaluating assertions between parties disagreeing on the truth value of a given statement, and many other logical tasks. By now, 'logic games' are a well-known technique, even in textbooks, for teaching logical basics. In particular, logical 'dialog games' suggest alternative views of valid reasoning in terms of winning and losing argumentation games, complementing the earlier views in terms of proof and semantics. The dialogical take on valid consequence employs the fundamental game-theoretic notion of a strategy, a response pattern for a player to any sequence of moves by one's opponents:

> *In fair rational debate, the proponent of the conclusion C has a winning strategy for upholding C against any play by an opponent granting the premises P.*

Logic games tie the study of reasoning to that of rational behavior in general. This is one of several places where logic interfaces with game theory, finding shared concerns in the

foundations of social action. The logic and games connection has led to new links of logic not only with philosophy but also with practical fields like argumentation theory.

Systematic Theory of Reasoning

With the rapid growth of nonstandard logics, the unity of classical logic may seem to dissolve. Even so, at a theoretical metalevel, unity may still prevail, be it in new more general guises – rather than the chanting of particular canonical laws of consequence. The usual mathematical notions and techniques of logic still work in today's broader realm, in charting possible systems, and exploring general trends. It is too early for a new synthesis of 'standard' and 'nonstandard,' but some unifying themes are noticeable.

Structural Rules

The above-discussed notion of nonmonotonicity is a hallmark of many nonstandard reasoning systems – although it is a symptom, not a diagnosis of underlying causes. However, there is a natural abstraction level here. In recent decades, it has turned out useful to classify styles of reasoning by their 'structural rules,' such as monotonicity and transitivity ('if P implies Q, and Q implies R, then P implies R'), and others, which move premises around, or duplicate them when needed. The structural rules of classical logic treat premises as an unordered set, whose presentation is irrelevant. By contrast, nonstandard reasoning tends to be more sensitive to the formulation of data, and the corresponding actions, which shows in failures of classical structural rules. Thus, in dynamic semantics, permuting two premises may change the update achieved – reflecting the typical order dependence of natural language. By now complete sets of structural rules have been found for many nonstandard reasoning practices, highlighting what makes them special. This variety has now also reached the philosophy of logic, where 'logical pluralism' is the position that this diversity is legitimate.

New Vocabulary

Reasoning and language are intimately connected. When an inferential practice changes, there may be a concomitant change in how we view the language where it all takes place. This language change can happen in two broad varieties. One is extension of classical languages. For instance, current dynamic logics of knowledge update or belief revision tend to add new logical operators of 'learning' connected to information changes, and then study their laws as an extension of existing logical systems. However, a more radical line is also noticeable in the current literature. A nonstandard notion of reasoning may lead to reinterpretation of the existing traditional logical operations. Thus, in logic games, a disjunction is a 'choice' of a move by the defending player, while a negation signals a 'role switch' between two players. Nonstandard reasoning may also involve new operations, outside the classical core. In particular, with games, there is not one conjunction, as in Boolean logic, but three: choosing which game to play at the start, playing one game after another, or playing two games concurrently. All these support logical laws for 'conjunction', that are related, but also part company in crucial aspects. Similar proliferation phenomena can be observed with the earlier mentioned resource-oriented proof-theoretic logics, from intuitionistic to linear systems. Thus modern calculi of reasoning can be much richer in vocabulary than classical logical systems: broader reasoning means richer language.

Again, theory is lagging behind agenda expansion here. The two strategies language extension and language reinterpretation seem to be connected in various ways. However, so far, we have only bits and pieces of translation results, and no general picture.

Mechanisms and Structures

More important than individual logical laws, deviant or not, are general mechanisms behind nonstandard reasoning systems. Striking unifying notions mentioned before included ordering relevant situations by various kinds of preference relations, fine-grained computational views of handling inferential resources, and natural repertoires of dynamic informational actions and processes. These notions provide a much richer picture of actual reasoning, and 'parameters' that can be set for different purposes.

Other important general trends go beyond the single-sentence habitat of standard logic. One of these is the temporal longer term. In addition to the usual local semantic 'meaning' of single inferences, acts of observation, or questions, there is the art of 'making sense' of these events. This art requires the setting of some longer term informational process, say a conversation, a process of inquiry, or a learning scenario. This was clear, for instance, with the game-theoretic view of validity that was discussed earlier: a strategy is a recipe for long-term behavior, guaranteeing certain outcomes in the long run. These temporal strategic aspects of reasoning are slowly coming to the fore in the modern literature, in the form of new research lines in between logic, process theories in computer science, and game theory.

Another large-scale aspect of reasoning that is ignored in a simple-minded premise-conclusion format is architecture of representation and processing. How are the data that reasoning has to work with usefully structured? How do different styles of reasoning cooperate to achieve useful effects? How do symbolic and nonsymbolic data (say visual, or just observing movement) cooperate in reasoning? One counterpart to the temporal long term here is spatial bulk. Reasoning takes place on the basis of experience, i.e., a vast reservoir of earlier reasoning tasks stored in some way in our memory (perhaps compressed into some sort of retrievable probabilistic version). How can we describe this, and what might be emergent statistical phenomena here going beyond our traditional idea of a logical system? Again, the earlier-mentioned interface between logic and probability becomes relevant here.

Finally, a pervasive theme in a broader understanding of reasoning is its social nature. Much reasoning is a many-mind activity involving agents that communicate, cogitate, and act – and the repercussions of this view of 'intelligent interaction' are slowly unfolding in current research on multiagent logics, computation, and games.

A Triangle of Disciplines

One way of looking at the nonstandard reasoning themes presented here is as a shift in character of logical theory, from purely normative to more descriptive. Now this may not be quite the right perspective: nonmonotonic logics can well be normative, and so can dynamic logics of observation, telling us what we should get out of what we see. However, what is true is that a natural triangle of disciplines is involved in most of the themes in this article. Some tend more toward theory (logic, philosophy, and mathematics), others are more driven by empirical data (linguistics or cognitive science), and interestingly, there was also a crucial third category of disciplines that are not easily classified as either normative or descriptive, such as computer science. Drawing sharp distinctions between the three kinds of discipline seems increasingly irrelevant in the study of reasoning.

Coda. Despite all this legitimate interdisciplinary variety at the level of cognitive activities, there may still be a privileged role for standard logic at another level. Significantly, in the metalevel system building about all these activities, logicians tend to follow classical methods from the field, since these have set standards of rigor and perspicuity that no one wants to give up. In this sense, there is much more continuity in the field than might appear from this article. The standard *modus operandi* is there to serve all.

Conclusion

Modern logic arose out of reflection on proof in mathematics and argumentation in philosophy, and created the standard systems of the twenty-first century. Modern studies of reasoning, while retaining the methods of this phase, deal with a much broader spectrum of laws, structures, and processes, than the repertoire of a standard logic textbook. Moreover, in doing so, they interface in new ways with disciplines such as philosophy, linguistics, computer science, cognitive science, game theory, argumentation theory, legal studies, and others. In this light, 'nonstandard reasoning' signals nothing marginal or subversive, except for insisting on this broader horizon.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

This article is a revision of the previous edition article by D. Offer, M. Sabshin, D. Albert, volume 14, pp. 9639–9645, © 2001, Elsevier Ltd.

Abstract

Concepts of normality are implicit in any description of health and disease. Although 'normality' is not itself defined, concepts of normality can be inferred from the concepts of health and disease. Normality as an ideal is described and then the varying concepts of disease are examined and reviewed. In psychiatry, these concepts are contested. The major and most influential theses of the fact, value, and concepts of mental disorder are examined and discussed. These include the contributions of Thomas Szasz, Christopher Boorse, Peter Sedgwick, Jerome Wakefield, and Robert Kendell.

Definitions of Normality

Definitions of normality go to the heart of medicine, its nature, and central concerns. It is how departures from normative values are defined and described that determines what the focus of interest of medicine ought to be. There is little doubt, too, that social context matters and that the definition of normality and by extension of disease and illness is constantly being negotiated between individuals, their doctors, and the wider society. It is also true that cultural beliefs and practices influence the manner in which medicine is practiced. In psychiatry, there is a further set of complications because the deviations from normative values are often, if not exclusively, behavioral deviations. This raises the profound problem of the boundaries of 'normal' behavior and whether aberrant behavior is evidence of disease or not. The history of psychiatry exemplifies the risk of identifying behavior that is socially disapproved of as evidence of disease. Behaviors such as masturbation, homosexuality, and slaves running away from their owners in the United States of America have all been designated as evidence of disease in recent times. Below is an examination of the various ways, in which disease is conceived in medicine starting with idealized concept of health promoted by the World Health Organization (WHO).

Normality as Idealized Norm

The WHO defines health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948). This definition does not define disease itself but rather, equates health with the complete absence of disease. Thus disease is a departure from this *ideal* state. But the absence of disease is itself not a state of health. In this description, not having any identifiable disease is not synonymous with health. The emphasis is not upon the absence of disease but rather upon some yet to be determined ideal state of 'complete physical, mental, and social well-being.' It is also significant that 'normality' too is not defined.

Disease as Departure from Statistical Norm

The statistical approach to defining what is a disease is best summed up as a disease is a quantitative deviation from the norm (Cohen, 1981). The application of statistics to population values as a basis for determining whether disease is present or not has the advantage that the data appear objective and the diagnostic process has at least a superficial precision. Since the determination of disease status is the product of mathematical calculation, it is therefore assumed to be objective, value-free, and reliable. This means that a diagnostic process that relies on such data is thought of as independent of any particular observer's opinion and preferences. Measurements of height, weight, blood pressure, intelligence, and so on fall into this category and departures from mean values as a basis of making diagnostic decisions exemplify this paradigm. Hence the diagnosis of obesity, hypertension, learning disability, and so on is determined by objective scores that can be fitted to a chart and shown to deviate from the mean values or to fall without two standard deviations from the mean. Child development charts that help to track the height and weight of a child and readily identify anomalies in growth, for example, derive their power and influence from this way of conceiving disease.

Disease as Lesion (Typology)

Rudolf Virchow (1821–1902) located disease within the cell and argued that diseases are the physiological outcome of altered conditions. More significantly, he had the notion that the cellular changes were observable under light microscopy and demonstrated characteristic phenomena that were both describable and invariant. This notion of disease-as-lesion was occurring alongside the germ theory of disease propagated by Heinrich Koch (1843–1927). Koch's postulates established the conditions for identifying a particular microorganism as the causative agent of disease. The contributions of Virchow and Koch were followed by spectacular triumphs as pathological anatomy and identifiable causative agents advanced the understanding of diseases. The characteristic lesion of pulmonary tuberculosis visualized under light microscopy following staining is an example of the power of a visual image denoting the pathophysiology of an infective process, rendering visible and recognizable what was until then invisible. Thus, this approach to diagnosis embodied the modern approach to scientific medicine, what has come to be termed the 'medical model.' This can be the promise of science as a method to

unravel the mysteries of diseases and to bring the complexities of disease processes under scrutiny and control.

Disease as Loss of Homeostatic Equilibrium

The realization that disease-as-lesion paradigm failed to explain many of the already known diseases led to further exploration of other notions of disease. Terms such as 'disorder,' 'dysfunction,' and 'maladaptation' refer to a recognition that there might be failures of function without identifiable lesions. Diseases such as migraine and trigeminal neuralgia cause distress and disability but occur without readily identifiable pathological anatomy. The idea that health is a state of internal homeostatic equilibrium and that loss of this equilibrium can result in disorder or dysfunction at least went some way in potentially explaining some conditions. The regulation of hormones by feedback loops (positive and negative feedback) and the effects of hormones on target organs at a distance from the site of the hormonal glands gave additional impetus to this notion of homeostatic equilibrium as an aspect of health. Thus disruption of the fragile homeostatic balance could result in disease without apparent lesions. Diabetes mellitus is the primary example of a disease that results from a dysregulation of homeostatic balance. Once the notion of homeostasis of the internal physical environment was grasped, it was only a matter of time for the potential disruption of the intricate relationship of the individual to his social and cultural environment to be recognized as a basis for disease. Thus, the external homeostatic balance between an individual and his physical and social environments could be envisioned as the context of health or normality and disruption of this balance could be conceived of as potentially causative of disease.

Disease as Social Deviance

The foregoing discussions about disease-as-departure from statistical norm, disease-as-lesion, and disease-as-loss of homeostatic equilibrium are often described as the 'medical model' of disease. Talcott Parsons (1902–79) argued that health is included in the functional needs of the individual member of society so that from the point of view of functioning of the social system, too low a general level of health or too high an incident of illness is dysfunctional. Disease in this formulation incapacitates the effective performance of social roles and there is, therefore, social interest in the alleviation of disease. To put this in another way, disease is not purely or merely a natural phenomenon but a state of disturbance of the total human being including the state of the organism as a biological system and of his personal and social adjustments. This approach introduces the notion that behavioral deviance itself can be the source of disease. But, how is such deviance to be recognized and defined. Social deviance can be recognized by self-definition. The individual may come to hold the belief that he has a problem or there may be a societal reaction that an individual's behavior constitutes a problem. Societal reaction of this type might occur when a community comes to recognize a person's inability or reluctance to respond in a particular expected way. According to David Mechanic (1968), "the view taken of the deviant depends in large part on the frame of reference of the observer and the extent to which the deviant appears to be able or willing to control his responses. The evaluator views the act within the context of what he believes the actor's motivation to be. If the action appears reasonable in terms of the assumed motivation of the actor, there is a very good chance that deviant behavior will be defined in terms of the goodness–badness dimension. If the behavior appears to be peculiar and at odds with expectations of how a reasonable person might be motivated, such behavior is more likely to be characterized in terms of the sickness dimension." The problem with this is self-evident. Disease definition in this formulation seems significantly prone to error, to subjective judgment, and liable to be used as a tool of social control.

The degree to which the recognition of psychiatric disorders relies on societal responses makes psychiatric notions of disease problematic if not controversial. This fact has been used by various critics of psychiatry as the basis of their case for the illegitimacy of psychiatric diagnoses and for emphasizing the extent to which psychiatric practice is an extension of society's mechanism for social control of its members. Application of theories and concepts of disease in psychiatry have faced widespread criticism. At the heart of the debate is the distinction between objectivity of science and the subjective value judgment of individual practitioners. The most fundamental issue, and also the most contentious one, is whether disease and illness are normative concepts based on value judgments, or whether they are value-free scientific terms; in other words, whether they are biomedical terms or sociopolitical ones (Kendell, 1986). Below is a summary of the main critiques and their contribution to the philosophy of psychiatry.

Critique of Disease Model in Psychiatry

Thomas Szasz

Thomas Szasz (1920–2012) argued that mental diseases are purely normative concepts and that they exhibit only behavioral symptoms and behavioral abnormalities and furthermore that psychiatric disorders do not have demonstrable physical causes and hence should not be treated by physical intervention (1974). For Szasz, *real* diseases are by definition bodily diseases, in which there are disturbances of function or structure of an organ or part of the body. Szasz develops his argument by appealing to Anthony Ryle's view that the notion 'mind' is a theoretical concept and that the term does not denote an organ or part of the body. So, Szasz concludes that the mind cannot be diseased in the same sense as the body can. This controversial viewpoint extends well beyond commonsense notions of disease because it has implications for whether psychiatric disorders such as schizophrenia ought to receive medical attention or not and whether crimes committed in the context of abnormality of mind ought to excusable or not. Psychiatrists have responded to Szasz's charge by arguing either that many 'physical' disorders lack established characteristic pathology or that mental symptoms and abnormal mental states are epiphenomena of underlying physical disturbances yet to be revealed (Clare, 1979).

At the root of Szasz's contention is the age-old mind–body problem. There is little doubt that brain diseases such as Alzheimer's dementia and Parkinson's disease that have an

established morbid anatomy often present with mental symptoms such as depression, anxiety, persecutory beliefs, and hallucinatory experiences. In other words, coarse organic brain disease can manifest as mental symptoms. It is therefore reasonable to assume that in the absence of coarse organic brain change, mental symptoms of this kind can be attributed to yet to be discovered functional abnormalities. It is also apparent that given the complexity of the brain as a conglomeration of neural systems, it will be prone to error and malfunction. Arguing that the brain is exempt from abnormality or that mental symptoms are invariably due to social and cultural causes is merely to deny the role of the brain in mental life. Notwithstanding the problem of mind–body duality and how to reconcile facts about the brain and the apparent independence of mental phenomena, there is an undeniable link between mind and brain.

Christopher Boorse

Christopher Boorse's distinction between disease and illness is deservedly influential. He argued that an organism is *healthy* at any moment in proportion as it is not diseased; and a *disease* is a type of internal state of the organism that interferes with the performance of some natural function, that is some species typical contribution to survival and reproduction. And, that the disease state is not simply in the nature of the species, i.e., is either atypical of the species or, if typical, mainly due to environmental causes. Diseases become illnesses only when they satisfy certain further, and normative, conditions. A disease is an illness only if it is serious enough to be incapacitating, and therefore is regarded as undesirable, a title for special treatment and a valid excuse for normally criticizable behavior. For Boorse, mental functions such as perceptual processing, intelligence, and memory clearly serve to provide information about the world that can guide effective action. Drives serve to motivate it. Anxiety and pain function as signals of danger, language as a device for cultural cooperation and cognitive enrichment, and so on. He concludes, "it seems certain that a few of the recognized mental disorders are genuine diseases, whether mental or physical. Even without any knowledge of the relevant functional systems, one can sometimes infer internal malfunction immediately from biological incompetent behavior." Finally, Boorse thought that diseases are what doctors treat and illnesses are what people suffer from (Boorse, 1976).

Boorse's approach avoids the problem that Szasz posed, namely, that mental symptoms do not derive from bodily disease. Boorse locates certain mental functions firmly within the domain of brain function and concludes that impairment of these functions speaks directly to brain malfunction. However, there are objections to Boorse's approach. For example, Fulford (2001) in an open letter to Boorse argues that a value-free naturalist account such as that by Boorse fails when it is applied to psychiatric disorders because psychiatry is concerned with "desires, beliefs, emotions, motivations and so forth, areas of experience and behavior in which human values are characteristically and legitimately *diverse*" (italics in the original). For Fulford and Sedgwick (see below), value-free descriptions of diseases are impossible.

The distinction between disease and illness that Boorse draws is also the subject of Kleinman et al. (1978) application of anthropological concepts to medicine. They argue that a disease is "malfunctioning or maladaptation of biologic and psychophysiologic processes in the individual; whereas illness represents personal, interpersonal, and cultural reactions to disease or discomfort" (Kleinman et al., 1978). Hence, illness is not merely a disease that "satisfies certain, further and normative, conditions" (see above) but it is "culturally shaped in the sense that how we perceive, experience, and cope with disease is based on our explanations of sickness, explanations specific to the social position we occupy and systems of meaning we employ" (Kleinman et al., 1978). In this scheme, illness is dominant in the patient's mind, as it is constituted of the difficulties in living that the patient experiences, whereas disease is the central focus of attention of doctors. Kleinman et al. (1978) conclude that both illness and disease are explanatory concepts that help to construct the forms of clinical reality that is faced in clinical practice. In this formulation, they anticipate Peter Sedgwick's views as described below.

Peter Sedgwick

Peter Sedgwick argues that "It may prove possible to reduce the distance between psychiatry and the other streams of medicine…not by annexing psychopathology to the technical instrumentation of the natural sciences but by revealing the character of illness and disease, health and treatment, as social constructions." In other words, all medicine is underscored by values. He goes on "The blight that strikes at corn or at potatoes is a human intervention, for if man wished to cultivate parasites (rather than potatoes or corn) there would be no "blight," but simply the necessary foddering of the parasite-crop." Furthermore, "A tiger may experience pain or feebleness from a variety of causes. It may be infected by a germ, trodden by an elephant, scratched by another tiger, or subjected to the aging processes of its own cells. It does not present itself as being *ill* except in the eye of a human observer." It is therefore clear that "The medical enterprise is from its inception value loaded; it is not simply an applied biology, but a biology applied in accordance with the dictates of social interest." Sedgwick concludes "All illness is essentially deviancy. That is to say, no attribution of sickness to any being can be made without the expectation of some alternative state of affairs which is considered more desirable. All illness, whether conceived in localised bodily terms or within a larger view of human functioning, expresses both a social value-judgement…and an attempt at explanation. The physicalist psychiatrists are wrong in their belief that they can find objective-disease entities representing the psychopathological analogues to diabetes." Sedgwick predicts that "*The future belongs to illness*: we are just going to get more and more diseases, since our expectations of health are going to become more expansive and sophisticated" (Sedgwick, 1982).

Sedgwick's position is that heart failure, for example, or any disease for that matter is of interest to doctors primarily because the symptoms are negatively valued – breathlessness, swollen ankles, general malaise, and premature death. These complaints, what Boorse would call illness, draw attention to a devalued state that is then the focus of medical attention, thus revealing a disease process that informs treatment. For Sedgwick, this process is as true for a physical disease such as diabetes as for a mental disease such as schizophrenia. Hence in his terms, there are no illnesses or diseases in nature. All illness,

whether conceived in localized bodily terms or within a larger view of human functioning, express both a social value judgment and an attempt at explanation.

Jerome Wakefield and Teleology

Jerome Wakefield's account is sometimes referred to as a 'hybrid account.' Like Sedgwick, he accepts that social values determine what symptoms are of interest to medicine. But unlike Sedgwick, he argues for *dysfunction* as a failure of a biological system: "a disorder exists when the failure of a person's internal mechanisms to perform their function as designed by nature impinges harmfully on the person's wellbeing as defined by social values and meanings" (Wakefield, 1992). This view is a variant on the criterion of biological disadvantage as the defining characteristic of 'disorder' set out first by Scadding (1967, 1990) and later by Kendell (1975).

Scadding (1990) made the point that "The name of a disease refers to the sum of the abnormal phenomena displayed by a group of living organism in association with a specific common charcateristics, or set of characteristics, by which they differ from the norm for their species in such a way as to place them at biological disadvantage" and Kendell (1975) elaborated this view by linking biological disadvantage to survival and reproductive fitness, namely, lowered fertility and reduced longevity. This proposition allows for disease status to be conferred by an objective judgment that the identified phenomenon places an individual at biological disadvantage either by causing premature death or by reducing reproductive fitness.

Wakefield's fully developed concept of mental disorder runs as follows: "A disorder is a harmful dysfunction, where 'harmful' is a value term, referring to conditions judged negative by sociocultural standards, and 'dysfunctional' is a scientific factual term, referring to failure of biologically designed functioning. In modern science, 'dysfunction' is ultimately anchored in evolutionary biology and refers to failure of an internal mechanism to perform one of its naturally selected functions" (Wakefield, 1992). Here, Wakefield is distinguishing between 'biological disadvantage' as enunciated by Scadding and 'failure of function' as described in his own approach.

The problem with Wakefield's position is that its explanatory power relies on a teleological argument: dysfunction can only be understood in relation to a goal, the *telos* of the function. And, it is often hard to comprehend what the biological goal of the identified function is, be it emotion, motivation, drive, or whatever. And, to attempt to explain an event, by describing the goal of that event is not equivalent to describing its cause. One of the characteristics of causal explanation is the temporal ordering of events – effects cannot precede their causes.

Summary

Normality is an important concept in medicine but is hardly ever directly defined. It is implicit in the WHO definition of health and concepts of 'normality' inform the various ways in which disease is conceived and defined. It is clear that *values* are important in the recognition of all diseases as entities falling under the interest of medicine but that objective, value-free explanations, that is, science informs understanding of disease processes. This is as true for 'physical' diseases as it is for 'mental' diseases.

Abstract

Norms are a major focus of attention of all social sciences, particularly sociology, political science, economics, anthropology, and social psychology. The social sciences are interested in the empirical study of norms, whereas jurisprudence and philosophy (moral philosophy and deontic logic) address the question of what 'good' norms are and how normative reasoning can be formalized. This article addresses the most important issues in the empirical study of norms.

We begin by outlining some basic facts about norms because explanations of norms should address these facts. Before proceeding further, it is useful to elaborate on the major dimensions of the norms concept that are found in the literature and to ask what norms definition is to be preferred. The next issue is how norms can be measured. The central theoretical questions are how norms originate and, if they exist, what effects they have. These questions are addressed in the last two sections of the article.

Norms are a major focus of attention of all social sciences, particularly sociology, political science, economics, anthropology, and social psychology. The social sciences are interested in the empirical study of norms, whereas jurisprudence and philosophy (moral philosophy and deontic logic) address the question of what 'good' norms are and how normative reasoning can be formalized. The literature on norms is so vast that a short article on this subject has to be restrictive. The following sections address the most important questions of the study of norms. We begin by outlining some basic facts about norms because explanations of norms should address these facts. Before proceeding further, it is useful to elaborate on the major dimensions of the norms concept that are found in the literature and to ask what norms definition is to be preferred. The next issue is how norms can be measured. The central theoretical questions are how norms originate and, if they exist, what effects they have. These questions are addressed in the last two sections of the article.

Some Basic Facts about Norms

When children grow up, they consider norms that are learned as universally valid. It is generally 'right' that one has to cover one's mouth when one yawns or that one must always tell the truth. But after some time, the child learns that there is a large heterogeneity of norms: different groups subscribe to different norms. This holds not only for immigrants but also for urban and rural populations or for younger and older people. The heterogeneity is still greater between countries. In India, for example, many people eat with their fingers. There is still female genital mutilation in several countries. In some countries like China tips are not given. Another basic fact about norms is that they change over time, in a given country as well as across countries. Some time ago it was scorned that women smoked in public. Foot-binding in China is no longer accepted. Another important feature of most norms is their conditionality. 'One must not lie' holds only under certain conditions. There may be white lies, that is, lies that avoid hurting others. In these situations, lies are allowed or even normatively expected. Another fact about norms is that they are related to each other. For example, a relatively general norm would be not to impose externalities on others. This implies or justifies the norm not to smoke in the presence of others, assuming that this hurts others. Norms vary in regard to their clarity. For example, under what conditions is what kind of 'self-defense' allowed? There are further many vague concepts in laws, especially in the constitutional laws.

So far the referents of norms were behavior in a wide sense, including thinking (one must not think of murdering somebody). There are further norms referring to beliefs (Christians must believe in God) or to goals, attitudes, and emotions ("Thou shalt not covet thy neighbour's wife," or "Love thy neighbour as thyself"). These facts are interesting in their own right, but also a challenge for explaining their origins and their effects.

The Definition of Norms

The literature abounds with definitions of norms. An overview and discussion of many norm definitions is provided by Gibbs (1965), Biddle and Thomas (1966), Rommetveit (1953), and Williams (1968). Crawford and Ostrom (1995) give a detailed analysis of the 'grammar' of norms. In this section, the dimensions of the norms concept that most definitions include are described, and it is discussed which definition of the norms concept is preferable. George C. Homans' definition of norms includes most of the dimensions that are ingredients of other definitions as well:

> A norm is a statement specifying how a person is, or persons of a particular sort are, expected to behave in given circumstances—expected, in the first instance, by the person that utters the norm. What I expect of you is what you ought to do (1974, p. 96).

Homans refers to four dimensions. One is oughtness: a norm is an expectation that some behavior ought to be (or ought not to be) performed. This is a basic characteristic that almost all norms definitions have in common. This is the oughtness definition of norms. A second dimension is that

people are expected to behave in a certain way 'in given circumstances'. Thus, norms may be conditional. A norm such as 'you shall not kill' holds only in certain circumstances or for certain kinds of actors (for example, soldiers are allowed to kill in times of war). Homans' definition further implies that norms refer to behavior, not to beliefs or attitudes. In contrast, Morris' definition (1956) also includes beliefs and attitudes (for examples see the first section). Fourth, the actors (i.e., the norm senders) who hold (or utter) a norm are individuals. In other definitions, the actors are collectives such as parliaments.

Two other criteria are used in many definitions of norms. Morris (1956) defines norms as "generally accepted, sanctioned prescriptions…" (p. 610). Thus, an expectation is, by definition, only a norm if the expectation is shared by the members of some group, and if conforming to or deviating from the expectation is sanctioned with some probability. It is important to note that a normative expectation is not identical to a preference. For example, I may not like it when you smoke in my company, but I may think that you are allowed to smoke.

A second type of definition – which may be called a behavioral definition of norms – states that a norm exists if there is a behavioral regularity and if sanctioning occurs with some positive probability in the case of deviating from this regularity. 'Sanctioning' means that others impose a cost on a person if a behavior is or is not performed. For example, a behavioral regularity may be that people keep promises. If someone does not keep a promise and if the person is sanctioned with some probability, then a norm exists. Refraining from a behavior may be a behavioral regularity as well. If people usually do not smoke (a 'behavioral' regularity) and if smoking triggers sanctions there is a nonsmoking norm. Thus, 'behavior' implies 'refraining from behavior'.

If a norm exists according to the behavioral definition, there need not be any element of oughtness. Assume that smoking is allowed (i.e., there may be no nonsmoking norm in the sense of the oughtness definition) and let nonsmoking be a behavioral regularity. Some nonsmokers do not like to be exposed to smokers. If this nonetheless happens smokers may be sanctioned: nonsmokers move to other tables in restaurants or express their anger about being disturbed. These actions may be costly to smokers, but they have nothing to do with a norm. Thus, although there is a behavioral regularity (most people do not smoke) and although there is some probability that deviations are 'sanctioned,' no norm is involved. Only if 'sanction' is defined as a reaction to the violation of a norm (in the sense of the oughtness definition) the behavioral definition includes oughtness. But most proponents of the behavioral definition do not like the oughtness definition because they prefer a pure 'behavioral' definition that allegedly allows easier measurement of norms (see below).

There are other definitions of norms in the literature. For example, Ensminger and Knight (1997, p. 2) define norms as "informal rules that structure behavior." Thus, only if a rule causes behavior can it be called a norm. If this definition is applied, it is no longer possible to explain a behavior by norms because a norm exists by definition only if it causes behavior. Since such definitions are relatively rare they will not be discussed here.

Laws (that will not be addressed in this article) are a subset of norms: they are norms that are promulgated by a public institution. There is a growing literature that explores differences between norms and laws (see, e.g., Posner and Rasmusen, 1999).

These definitions of norms are often used for defining institutions. The latter term often refers to single norms, as the following definition illustrates: "an institution is a regularity of behaviour or a rule that is generally accepted by members of a social group, that specifies behaviour in specific situations, and that is either self-policed or policed by external authority" (Rutherford, 1996, p. 182). 'Institution' often also denotes sets of norms as well as organizations (for a discussion see Calvert, 1995, pp. 216–218).

What definition is to be preferred? It is striking that despite the multitude of definitions in the literature, authors usually do not give reasons for preferring a certain definition over others. One important criterion for choosing a definition is the extent to which it refers to the explanatory problems social scientists want to solve. With regard to norms, social scientists are interested in explaining, among other things, when people accept normative expectations and under what conditions what kinds of sanctions are attached to normative expectations. Answering these questions is not possible if several dimensions of norms are included in a single complex definition. In those definitions, certain combinations of values are contained (such as existence of a behavioral regularity and a positive probability of sanctioning). Thus, only this combination of values can be explained. The upper part of Figure 1 depicts this situation.

However, it is also important to know how the dimensions are causally related (see the lower part of Figure 1). For example, if norms are shared and if strong sanctions go with the norm, it is likely that the behavior that the norm prescribes is performed. These complex interdependencies cannot be addressed if several dimensions are incorporated into a single

Figure 1 Different procedures for explaining the origins of norms.

definition. Treating the dimensions separately allows us to explain them and look at their interdependencies (for a similar argument see Hechter and Opp, 2001, p. 404).

It is further important that the definition used has theoretical import: it must permit the formulation of true and informative theories. The extent to which this criterion is fulfilled can only be judged if a theory with the respective concepts exists and has been tested. As long as such a theory does not exist, the definition is a preliminary working definition.

The concept of sanction has also different meanings in the literature. It may refer to a behavior that is intended to change a future behavior of a norm breaker. Sanctioning may also refer to a behavior that actually influences the future behavior of a person. Any reaction to a behavior – that need not be related to norms – is also sometimes denoted as a sanction. Researchers who use the sanction concept rarely specify its meaning. What is a theoretically fruitful sanction concept? This question is not addressed in the literature.

How Can Norms Be Measured?

If historians want to get information about norms they will look at documents such as books about manners (see, e.g., Elias, 1994). To learn about the norms of a cohort of young people, sociologists may analyze their diaries. The norms of voluntary associations may be taken from their statutes. One problem with these sources is to what extent the written norms are or were actually in effect. Diaries may only reflect the norms of a specific group of middle class youths. Books of manners may describe rather the ideals of the author than the manners that are effective. Another problem is the extent to which written documents state the conditions under which a norm holds. Members of a group may often not be aware of those conditions so that it is questionable whether documents state a given norm in all its complexity.

It seems that the method of observation is especially suitable for ascertaining norms according to the behavioral definition: behavior, in contrast to expectations, can be observed in principal, but practically, this is often difficult. It is not easy, for example, to measure the frequency of promise keeping (or of breaking promises), of certain sexual behavior, or of smoking. It is practically impossible to observe these behaviors for a large group: numerous observers and intrusion in the private sphere would be necessary. Even if these difficulties can be overcome, recording the behavior (even on a videotape) is not sufficient. A given behavior may have quite different meanings. For example, making a promise is a verbal behavior and the observer must know the language of a group in order to ascertain the extent to which promises are made or kept. Many kinds of sanctioning are verbal behaviors as well, and a given behavior may have different meanings. Shaking of the head may express disapproval but may also be a sign of astonishment. Thus, although behavioral regularities and sanctioning are in principle more accessible than expectations, practical measurement by observational techniques is extremely difficult. The conclusion is that the measurement argument that is often invoked for a behavioral definition is very questionable.

Surveys are probably used most frequently to measure norms. There are different procedures. For example, Jackson (1966) measures the extent of approval or disapproval of a behavioral dimension (such as the extent of approval of the number of times a person speaks in an hour's session of a discussion group). If 'frequency of behavior' is plotted on the x-axis and average approval/disapproval of the members of a group on the y-axis, a curve or line shows what behavior is more or less approved or disapproved. Based on such a curve various statistical measures can be computed. Another measurement procedure is to formulate various items that are designed to capture, among other things, the conditionality of a norm. For example, one of the items used to measure protest norms reads: "nobody can be expected to take part in political actions that might send her or him to jail" (Opp and Gern, 1993, p. 668). A third measurement device is the factorial survey that seems best suited to ascertain the conditionality of a norm. The first step is to specify the conditions under which a norm holds. For example, people may endorse an obligation to protest if the expected repression by police action is low or if the expected success of the collective action is high. Thus, the dimensions 'expected repression' (with values 'no' or 'yes') and group success (with the same values) may be important conditions for a felt obligation to protest. As a next step, descriptions of situations (the vignettes) are constructed from all possible combinations of the dimensions. Each of these situations is then judged by the respondents of the survey: they are asked to what extent a behavior (such as participating in a demonstration) is more or less obligatory in a given situation. The data enable the researcher to ascertain what effect each of the dimensions has on the overall normative judgment performing certain actions under a whole set of conditions (for details see Jasso and Opp, 1997; Opp, 2002).

Qualitative researchers may in general object that norms are not given but are largely 'constructed' in specific situations (see, e.g., Fine, 2001). This implies that the measurement of norms is impossible because they do not exist. Survey research does not confirm this view. If norms do not exist, the prediction is that factorial surveys yield a large number of missing values, which did not turn out to be the case (Jasso and Opp, 1997; Opp, 2002). It is surprising that despite the centrality of norms in the social sciences, there is rather little effort to develop standardized measurement procedures of norms. A detailed comparative discussion of the different procedures is also missing.

The Origins of Norms

The major difficulty of reviewing theories about the emergence of norms is the great variety of propositions, scattered in the literature, and the diversity of theoretical approaches. Recent reviews of the so-called new institutionalisms (see, e.g., Hall and Taylor, 1996) testify this. Nonetheless, a review of various propositions and approaches indicates that there seems to be one basic idea that underlies all or at least most explanations of norms. This is the instrumentality proposition. The idea is that norms emerge if their emergence is in the interest of a collective of people. A major proponent of this idea is Robert Ellickson who "advances the hypothesis that when people are situated in a close-knit group, they will tend to

develop for the ordinary run of problems norms that are wealth-maximizing" (1989, p. 84; see also 1991). Norms are thus instrumental (Opp, 2001). It is important to distinguish the instrumentality proposition from a functionalist hypothesis claim that norms emerge if they contribute to the equilibrium or survival of a social system. This hypothesis is flawed because it is not possible to explain the existence of some item by the effects that it would have if it existed. Such functionalist arguments are still widely used in the literature (see the critique by Hardin (1980) of Ullmann-Margalit (1977)). In contrast, the instrumentality proposition holds that situations or events that jeopardize the realization of group goals of actors provide incentives to the actors to create rules that make the group better off.

The instrumentality proposition is consistent with the widely held view that the emergence of norms is likely if there are externalities. These are actions that incur costs (negative externalities) or provide benefits (positive externalities) to other actors. Those who are affected by negative externalities have an interest in establishing norms that reduce the externalities. Those who cause positive externalities have an interest to establish a norm that compensates them. The basic reference for this theory is Demsetz (1967) (for a discussion see Eggertsson, 1990). This theory underlies Coleman's explanation of norms (Coleman, 1990, Chapters 10 and 11).

Norms are public goods, that is, goods that if provided are consumed (or enjoyed) by every member of a group even if the member has not contributed to their provision. For example, a nonsmoking norm holds for everybody. Public goods theory, which is consistent with the instrumentality proposition, argues that "groups exist in order to supply their members with some desired joint good. This good can be attained only if members comply with rules that are designed to assure its production" (Hechter, 1987, p. 41; see also Oliver, 1980; Heckathorn, 1990; Coleman, 1990). Thus, norms are instrumental in achieving group goals: norms are (second-order) public goods that are instrumental for providing (first-order) public goods.

There are different mechanisms that lead to the emergence of norms. Often, norms emerge by human design such as laws. Assuming that individuals have biased knowledge about the effects of their actions (a lawmaker may issue a law that is not accepted or has unintended negative side effects), it happens that norms are inefficient. This means that alternative norms would make the members of a group better off.

Inefficient norms may also originate due to path dependence (see, in particular, Arthur, 1994; Mahoney, 2000). In its most general sense, this means that the mere existence of norms or institutions heavily influences costs and benefits of change. Even if the Dvorak keyboard would allow much quicker typing than the QWERTY keyboard replacing the latter with the former would be very costly (see David, 1985; Lewin, 2002).

Kitts (2006, 2008) has conducted computer simulations showing that a regulatory interest (Heckathorn, 1988) as a condition for the emergence of norms may decline if selective incentives are rival. This means that the provision of a selective incentive to one member of a group diminishes its value to other members. These will then no longer be motivated to contribute to the collective good but enforce "antisocial norms that discourage peers' work" (Kitts, 2008, p. 143). Reference is here made to norms at the workplace. In this scenario, workers act 'instrumentally' as well, but their action will lead to norms that are likely to have negative effects for the workers themselves as well as for the firm.

We find the instrumentality proposition also in the work of qualitative sociologists. Fine (2001) explains why there is a norm that restrains mushrooming. He notes that mushrooming is competitive: if someone picks a mushroom another one cannot. Mushroomers are thus exposed to a negative externality. In this instance, the norm 'first come, first serve' might apply. However, this solution would breed strain. Mushroomers were interested in good personal relations that were inconsistent with an untamed competition. Thus, the emergence of a norm about constraining the collection of mushrooms is, among other things, due to the goals of the group of mushroom collectors.

Norms are often not the result of human design but the unintended and sometimes undesired consequences of human action. The emergence of such 'spontaneous' norms is consistent with the instrumentality proposition as well. Assume that all of a sudden being exposed to smokers becomes a strong externality for nonsmokers. They will increasingly punish smokers. Nonsmokers may be interested in the production of a 'private good' (being free of smoke) and not in establishing a general nonsmoking norm. Due to extensive sanctioning behavior, smokers will increasingly stop smoking and will get a bad conscience when they smoke in the presence of nonsmokers. A general nonsmoking norm has emerged. Various other mechanisms of the spontaneous emergence of norms are described in the literature. See particularly the literature on conventions (Schelling, 1960; Lewis, 1969; Sugden, 1995). Other examples of the spontaneous emergence of norms are explored by Mackie (1996), Opp (1982, 2002), and Horne (2001).

The instrumentality proposition assumes 'instrumental rationality' in the sense that individuals have goals and perceive that a norm x generates outcomes that attain their goals. Boudon (1997, pp. 19–22) argues that "many moral feelings are not the product of instrumental rationality" (p. 20). For example, the act of stealing cannot be shown to have negative consequences; stealing is bad because it contradicts basic moral principles. However, the instrumentality proposition does not rule out that the goal of a group or of individuals is to preserve general social principles (or values). The instrumentality proposition (and the theory of rational action in general) assumes 'instrumental rationality' or 'consequentialism' in a wide sense: a behavior (or a norm) may be instrumental in the sense that its aim is to influence phenomena outside the individual (such as to make other people better off) or to achieve goals related to internal states (such as following a norm). For details see Opp (2013).

Sociologists usually explain norms by the socialization proposition claiming that norms are transmitted (see, e.g., Boyd and Richerson, 1985). This may occur spontaneously (a norm is imitated) or in a planned way (parents socialize their children). One question that the socialization proposition does not address is under what conditions people transmit norms. Whatever these conditions are, sociologists seem to argue that it is not the overall instrumentality of a norm for a group that

is transmitted. This is suggested by the fact that norms may be dysfunctional (Merton, 1968, Chapter 3) and nonetheless spread. However, one would expect that parents who socialize children (or members of a group who socialize new members) are driven by incentives, that is, by their personal goals (Coleman, 1990, Chapter 11): parents teach their children good manners because they think that this is in the interest of the child or because they do not want to get a reputation of being bad parents who are not able to teach their children how to behave. Thus, parents aim at providing a private good ('good' children) that might lead to a norm on the macro level. The socialization proposition further does not specify how norms emerge before they are transmitted.

It might be argued that the previous propositions are inconsistent with a cultural approach such as symbolic interactionism. Hall and Taylor (1996) argue that a cultural approach does not reject that individuals are purposive, goal oriented, or rational (p. 949). But, they argue, the goals of individuals are conceptualized much broader: not only material well-being is at issue but individuals or organizations are also assumed "seeking to define and express their identity in socially appropriate ways" (p. 949). This critique holds for a narrow neoclassical version of rational actor theory but not for a wider version (Opp, 1999) that includes goals that go beyond material well-being. For example, preserving one's 'identity' may mean that members of a group subscribe to the goal of acting in accordance with important others. Furthermore, invoking 'world views' as conditions for norm emergence is also not against a rational choice approach because actors may realize that certain norms contradict values, and this may be a cost that discourages the acceptance of a norm.

The Effects of Norms

Assume that a norm has come into existence. What effects does the norm have on persons' actions? Role theory posits that norms are organized in roles that individuals take over. For example, the role of 'father' consists of a set of normative expectations about what a person with this role has to do and not to do. The message of the homo sociologicus is that individuals behave according to their roles (see, e.g., Biddle and Thomas, 1966). There are several problems with this proposition. One is that behavior that is not regulated cannot be explained. For example, there is no norm prescribing that one should not go to a cinema and instead watch television. A second problem is that the proposition is wrong – people often deviate from role expectations. 'Homo sociologicus' cannot explain such deviations. A third problem exists if there are conflicting role expectations: the theory does not tell us what expectation is heeded. The basic assumption of this theoretical orientation is that individuals are socialized into their roles and follow them blindly.

An alternative to this oversocialized conception of humans (Wrong, 1961) is to assume that in situations in which norms hold there is choice – as in any other situation. Individuals realize that they have at least two options: to follow or not to follow a norm. Each of these options has certain costs and benefits, depending on the situation. If norms are internalized, this means that breaking a norm ensues in a bad conscience, which is a cost. The severity and probability of external sanctions, including informal sanctions, are costly as well (see, e.g., Epstein, 1968; Hechter, 1984; Heckathorn, 1990; Posner and Rasmusen, 1999). But other nonnormative costs and benefits may instigate an individual to break a norm. What exactly the costs and benefits are that govern behavior if norms are given depends on the explanatory problem and cannot be specified in advance. For example, when people consider divorce, marriage norms play a more important role in Catholic than in Protestant countries. In committing murder norms may be more important than in tax evasions. In both situations, the kinds of nonnormative costs are very different. Thus, in explaining the effects of norms one has to include other nonnormative incentives and recognize that often norm following is a decision situation. This argument is based on the 'homo oeconomicus.' It suggests that homo sociologicus does not contradict homo oeconomicus.

To be sure, an individual has always a choice to follow a norm or break it. But often, the choice is made automatically, i.e., without thinking about the available options in a specific situation. To illustrate, let a person move to a new apartment and consider the possibilities of reaching the workplace. After weighing several alternatives, the person decides to take the subway, for the time being. It often happens that at some time a person makes a decision to act in a certain way and then performs the same action without deliberating. The action then becomes a habit – until there are certain changes in the situation (e.g., the subway schedule becomes unreliable). In regard to norms, it also happens that deviating from a norm is so costly that this action is never considered. This type of situation indeed resembles the situation that role theory seems to portray. But even if a behavior is normatively regulated, nonnormative incentives may be relatively strong so that the available options are weighed. When the effects of norms are considered, it is useful to distinguish between two types of effects. One concerns the direct effect of norms: compliance. If a norm (and the pertinent sanctions) has emerged, more people perform the behavior that is in accordance with the norm than before. If, for example, a government prohibits civil servants to smoke at their workplaces, smoking at the workplace will decrease.

This example illustrates a second type of indirect effect of norms. If fewer civil servants smoke, this may instigate others to stop smoking as well. This will reduce the number of people who get cancer and, thus, expenditures of health insurance companies will decrease. Indirect effects are often subtle and difficult to discover. For example, if companies have to pay increasing benefits to employed women (such as time off before and after pregnancy that the employer has to pay), the costs of employing women increase. The effect may be that in the long run unemployment of women increases and salaries decrease. This would certainly not have been intended by those who made the law. Increasing punishment for some crimes may amount to a higher relative benefit of committing other crimes and thus may lead to a displacement effect. In general, changing norms may change the costs or benefits of various types of actions and may thus have unanticipated and undesired indirect effects. What the indirect effects of norms are

cannot be said in advance. A detailed analysis of the incentives that prevail in the situation for which the effects of norms are to be explained is necessary.

Norms in Science

Peter Weingart, University of Bielefeld, Bielefeld, Germany

Abstract

It is generally recognized that communication among scientists and scholars is governed by a particular scientific ethos, that is, by a set of rules that are supposed to establish trust in, and guarantee the reliability of, the knowledge created in the process. This ethos, although rarely made explicit in science, was given its most succinct and influential formulation by the American sociologist of science Robert K. Merton who defined it in terms of four basic norms and with that laid the groundwork for the *Sociology of Science*. This article presents the norms, their significance in scientific and scholarly communication, and some criticisms challenging their actual existence/validity motivated either theoretically or by factors related to the changing nature of science.

Introduction

It is generally recognized that communication among scientists and scholars is governed by a particular scientific ethos, that is, by a set of rules that are supposed to establish trust in, and guarantee the reliability of, the knowledge created in the process. This ethos, although rarely made explicit in science, was given its most succinct and influential formulation by the American sociologist of science Robert K. Merton (1957 [1942]), who defined it in terms of four basic norms, and with that laid the groundwork for the *Sociology of Science*. This article presents the norms, their significance in scientific and scholarly communication, and some criticisms challenging their actual existence.

The Norms of Scientific Communication

The scientific ethos refers to those patterns of behavior and implicit norms among scientists that can be traced back in history to the establishment of the academies in England and France in the seventeenth century. Regardless of many changes in detail there is a remarkable continuity in this ethos over a period of more than three centuries. Merton's formulation of the norms of science can be understood as an analytical condensation of the behavioral patterns that evolved over the duration of this period into a set of institutional imperatives or norms. The ethos, in his words,

> 'is that effectively toned complex of values and norms which is held to be binding on the man of science' and which, although not codified, can be inferred from, above all, the 'moral indignation directed toward contravention of the ethos.' (Merton, 1957: pp. 551–552)

The four key norms, according to Merton, were the following:

1. Universalism is the principle that truth claims are 'subjected to preestablished impersonal criteria' (Merton, 1957: p. 553) irrespective of the social attributes of their protagonists, for example, nationality, race, class, or religion.
2. Communism (later and preferably termed 'communalism') refers to the norm that the findings of science 'are a product of social collaboration and are assigned to the community' (Merton, 1957: p. 556). Property rights are kept to a minimum, and the scientist's claim to intellectual property may only be exchanged for recognition and esteem by the members of his community.
3. Disinterestedness demands that scientists should resist the temptation of using improper means (such as fraudulent manipulation of data) in the search for and communication of 'true' knowledge to their own advantage. It is a fundamental institutional element that has its basis in the public and testable nature of science, and it contributes to the integrity of scientists through accountability to their peers.
4. Organized skepticism is 'both a methodological and an institutional mandate.' It refers to the scrutiny of claims and beliefs by scientists' peers on the basis of empirical and logical criteria (Merton, 1957: p. 560).

These norms or values are interrelated and together shape a system of communication that is uniquely geared to produce knowledge that may be considered 'true' in the sense of being reliable, but by no means final. Universalism guarantees, at least formally, general social accessibility and at the same time it prevents the intrusion of any other criteria (political, religious, ethnic, etc.) in the communication of knowledge other than the certified knowledge accepted as belonging to science itself. Communalism subjects all knowledge to general and open communication, thereby subordinating the proprietary interests of the scientist to the less tangible rewards of gaining recognition by obtaining priority of discovery. It contributes to the social cohesion of the scientific community. Disinterestedness constitutes the self-reference of scientific communication. This means that science differs from other professions in that it has no clientele. The clients of science are scientists themselves; since all are engaged in a communally beneficial search for truth, and fraud or quackery may lead to temporary advantages at best. Organized skepticism is the reverse side of the norm of disinterestedness, as it stipulates the impersonal scrutiny of any claim to truth as a general principle of scientific communication. It is institutionalized in the peer review system of journals and funding agencies.

Merton's list of the norms of science was one of several descriptions of the 'scientific ethos' formulated during the late 1930s and early 1940s in reaction to the threats against science and democracy by fascist states in Europe (Hollinger, 1983). Merton's own account was written, originally in 1938, in reaction to the direct political interventions in science in National Socialist Germany (Merton, 1938; Mendelsohn, 1989). Later treatments of the scientific ethos have largely ignored this peculiar historical (and ideological) context of its formulation and have focused on its sociological relevance. Bernard Barber, working in the structural-functionalist tradition of Talcott Parsons and Robert Merton, added three values to the list of norms: faith in the virtue of rationality, 'emotional neutrality as an instrumental condition for the achievement of rationality,' and 'individualism' (Barber, 1953: pp. 86, 88). However, partly because of their overlap with the Mertonian norms and partly because of their different theoretical status, they never attracted the same attention.

The Theoretical Status and Significance of the Norms in Sociology of Science

In order to appreciate the significance of the norms one has first to realize that science in its modern form, as an institution that has the goal of the 'extension of certified knowledge' (Merton, 1957: p. 552), is an unlikely social invention. The improbability lies in the fact that science emerged from a historical situation in which the production of knowledge was immediately linked to the glorification of God or to the pursuit of economic utility. The unprecedented progress of science began when it became a 'self-validating enterprise' (Merton, 1957: p. 551), that is, a separate functional subsystem of society (Luhmann, 1990). On the institutional level, the remarkable social innovation was the separation of social status, religious affiliation, and, above all, prestige from the communication of truth claims. The rules and principles, which have been poignantly dubbed 'technologies of distance' (Porter, 1992), were instrumental in creating trust in scientific communication. They were gradually extended from individuals to institutions, allowing for a communication network that reached beyond generational limits in time, as well as beyond the social and geographical limits of personal acquaintances. Historically, the process of the formation of modern science spans from the seventeenth century to the early nineteenth century when the university emerged as the core institution and disciplines formed marking the establishment of self-validation and autonomy (Stichweh, 1984). Merton's norms codified the institutional patterns that emerged during this period into an analytical scheme that served to explain the unique status of science – as a set of methods to produce certified knowledge and to accumulate the knowledge that accrues from their application, as well as a set of cultural values and customs that governs these activities.

Thus, with the articulation of the norms, Merton also defined an aim for sociology of science: to be concerned primarily with the moral compulsion of methods and their impact on behavior, not with their technical expediency. Merton, in effect, conceived of the sociology of science as an analysis of the social prerequisites and institutional configurations of science. Sociologists would in no way be concerned with the substantive findings of science or their methodological underpinnings. Consequently his sociology never challenged the philosophical assumptions that shaped the concept of science at any particular historical moment, and which have changed over time; a limitation for which his views were subsequently criticized. Under the influence of Thomas Kuhn (1962), sociologists began to look into the normative nature of scientific paradigms and thereby crossed the line into a full-fledged 'sociology of scientific knowledge.' The theoretical status of the scientific ethos has been a persistent issue. It often has been argued that scientists do not behave in accordance with these norms and that the norms themselves are subject to historical change (Barnes and Dolby, 1970). Somewhat related to this is the critique that the norms are an edifying portrait of science that functions less as a description of actual behavior than as a professional ideology that has supported the post-World War II rise and establishment of 'basic science' (Mulkay, 1976). However, the existence of norms is not necessarily reflected in actual behavior. Merton's theoretical construction of the norms is a complex combination of different elements: (1) sociopsychological patterns of attitudes that are expressed in internalized (but not necessarily explicit) reactions to violations of the norms, in the awareness that one's own actions or those of others are breaching a code; and (2) sociostructural patterns of sanctions, that is, mechanisms institutionalized in science that sanction, positively or negatively, certain behaviors like plagiarism (negatively) or the open exchange of information (positively). Thus, to demonstrate whether the norms are operating or not, requires a more sophisticated approach than mere observation of behavior.

Merton himself responded to the challenges to the validity of the norms by pursuing two research strategies: (1) the analysis of apparent paradoxes in scientists' behavior and the resulting psychological and social conflicts (Merton, 1973b); and (2) the study of typical reasons for attacks against science or for conflicts between science and its societal environment (Merton, 1957 [1942]). On the one hand, Merton observed a peculiar ambivalence among scientists toward priority disputes and their own interest in priority of discovery. (His empirical evidence consists of biographical materials and correspondence of scientists dealing with priority disputes.) He attributed this ambivalence to the institutional mandate of disinterestedness and the primacy of the expansion of knowledge. Here again, sociological elements are coupled with sociopsychological ones. The need for recognition felt by the individual scientist is not an expression of idiosyncratic vanity but is initiated by the institution. 'Continued appraisal of work and recognition of work that was well done constitute one mechanism that unites the world of science' (Merton, 1973b: p. 401). Merton reacted to the changes in sociopsychological patterns affected by institutional changes. Observing the increasing number of multiauthored journal articles that indicate the rising importance of cooperative forms of research, he concluded that the 'interest in priority' – by no means historically invariant – may give way to an interest in the recognizability of one's work in a research team (Merton, 1973b: p. 409).

Merton's second approach to documenting the validity of the scientific ethos was to analyze conflicts between science and its societal environment. He observed two sources of hostility toward science: the conflict between methods or important results of science with important social values, and the conflict between the sentiments embodied in the scientific ethos and those of other institutions (Merton, 1957: p. 537). The most obvious conflict of the latter type arises in totalitarian political orders – the kind Merton had in mind at the time of his original writing. This was a conflict between the scientific ethos and the political code that routinely discredited science as 'cosmopolitan,' 'liberalistic,' or 'bourgeois.' (In his 1938 and 1942 essays Merton focused on Nazi Germany, after the war he included the Stalinist regime in the Soviet Union epitomized by the Lysenko affair.) A more complex effect may be seen to accrue from utilitarian demands on science. Originally in opposition to the demands of the church, the state, or the economy, the orientation to 'pure' science may undermine the social esteem of science. Although this purist orientation may be methodologically justified, as it minimizes bias and error by separating the production of knowledge from its application, its social effect may be resentment and revolt against the possible negative consequences of science (Merton, 1957: pp. 543–545). This diagnosis has proven to be farsighted. Since the 1960s, public resistance to and critique of technological projects have steadily increased and the social contract for 'pure science' has come under pressure.

Merton's formulation of the scientific ethos as a description of the special nature of science as an institution has been fruitful in two ways. On the one hand, it focused on the effects of structural changes in science, on the institutional mechanisms that guarantee the production of certified knowledge through channeling scientists' behavior. On the other hand, it focused on the conflicts that emerge between science and other institutions. The question then is what becomes of the scientific ethos as science and its institutional context change over time?

The Scientific Ethos and the Changing Nature of Science

Critics of Merton have pointed to the many changes science has undergone that are not accounted for in an ethos that is basically geared to an individualist concept of gentlemanly science. Merton himself addressed these changes and granted some plausibility to the view that the customs of scientists must have changed in view of the fact that all the "basic demographic, social, economic, political, and organizational parameters of science have acquired dramatically new values" (Merton, 1973a: pp. 328–329). He enumerated certain typical phenomena such as the premature publication of results before a theory is corroborated by more careful competitors, and an intensified rivalry occasioned by specialization as well as a new kind of cynicism, amorality, and disillusionment that goes along with it. However, in Merton's view, scientists' interest in priority, as such, has not changed. Rather than indicating a change of the ethos, public reactions to apparent or real breaches of the ethos reveal an 'instructive paradox,' namely, that the 'customs governing the public demeanor of scientists and the public evaluation of contemporaries have become more exacting rather than less' (Merton, 1973a: p. 338). Merton's observation is supported by heightened concerns in governments and the media about spectacular cases of fraud in science since at least the 1980s. Although it is by no means a proven fact that the incidence of fraudulent behavior among scientists has increased the structural pressures on scientists, especially in highly dynamic and capital-intensive research fields (e.g., biomedicine) and the concentration of reported cases in them suggest that it has increased. As a result, public awareness and vigilance have intensified. In several countries, institutions have been set up to monitor and sanction 'misconduct' in science (e.g., the Office of Research Integrity in the United States), and it is noteworthy that the 'codes of conduct' underlying their operation either explicitly refer to Merton's norms or are highly consistent with them.

Some theorists have suspected that the ethos of science is threatened by fundamental changes in social values. Yaron Ezrahi sees a challenge to the scientific ethos and to liberal democratic values by the counterculture that emerged from the radicalism of the 1960s, which favored values such as personality, authenticity, and creativity without standards. The belief that science is an enterprise governed by universalistic norms that produces objective knowledge by abstracting from its bearers is replaced, in his view, by an individualization of the perception of reality and the production of knowledge (Ezrahi, 1990: p. 54). In a similar vein, Paul Forman focuses on the effects of postmodernist values on science. He observes three main changes in the production of knowledge as causing the spread of these values: overproduction of knowledge and a resulting plurality of standards; instrumentalization of knowledge effecting an ethos of production as an end in itself; and an affirmation of knowledge as 'bound' and 'interested' resulting from an alleged incommensurability of different stocks of knowledge (Forman, 1997).

Another threat to the scientific ethos is seen to emerge from the 'commercialization' of science, mainly in the form of patenting and the imposition of licenses and other forms of intellectual property rights (IPR), together with their impact on the 'culture' of open academic science. It is plausible to assume – and in some cases has been shown to occur – that an undue orientation among scientists to monetary profit potentially violates the norms of communality (by way of delaying or interrupting the communication of research results through IPRs), organized skepticism, and disinterestedness (e.g., as a result of monetary conflicts of interest in review processes) (Mirowski and Sent, 2007). The underlying conflict is seen as occurring between 'public' and 'private' science.

Whether or not these diagnoses are correct will ultimately be verified by observable changes in the scientific ethos and by the emergence of radically different patterns of the production of certified knowledge. Merton's formulation of the scientific ethos has provided invaluable groundwork for an understanding of the interaction between normative, psychological, and institutional mechanisms in the production and communication of scientific knowledge.

Abstract

The archaeology of North America includes at least 16 000 years of occupation. The archaeological record is the product of communities of diverse cultural practices and worldviews who negotiated social and ecological environments. Although it contains evidence for many social and technical strategies, the archaeology of North America has much to contribute to contemporary and future concerns with climate change and the reconstitution of communities.

North America has an unbroken record of human occupation dating back at least 16 000 years. North American archaeology explores the ecological, political, and social dimensions of human experience recorded in material traces of past activities. Encapsulated in North America's history of occupation are processes of migration and interaction among culturally diverse communities. Many regions witnessed the emergence of complex societies whose political and economic institutions were materialized in objects and constructed landscapes. The development of traditional ecological knowledge and landscape management practices enabled communities to be resilient to environmental change, but also made some communities vulnerable to climatic or social perturbations. Finally, North American archaeology today is concerned with cultural heritage and the significance of the past, today, and in ancient times.

The archaeological record of North America is composed of the various objects, structures, and landscapes that humans created or interacted with. The most frequently occurring objects are tools made of stone and the debris generated during their manufacture and use. Vessels manufactured from ceramic, as well as items made of stone, marine shell, basketry, or textile were also produced in some regions. Many items of personal adornment are also known. Where conditions allow, the archaeological record contains objects manufactured from organic media (bone, wood), in addition to the remains of meals. The distribution of these various materials reflects accommodations of communities to particular social and ecological environments, as well as trade and interaction between groups. Archaeological sites in North America vary from the small scale of object scatters up to the large scale of ancient and modern cities, such as the thousand-year-old site of Cahokia near modern-day St. Louis, Missouri. Places of social poignancy and reverence are widespread through time and across space. Places of social significance include mortuaries, earthen or shell monuments, caves and rock shelters, and petroglyph panels. Included here as well should be 'natural places' that remain mostly unmodified but which were nonetheless significant to ancient communities and their descendants (Zedeño et al., 2009). A wide spectrum of societies has been documented in the region, whether one categorizes them by subsistence economies (hunter–gatherers, cultivators, and intensive agriculturalists), political economies (bands, tribes, chiefdoms, states, and empires), or historical processes (communities that are coalescent, diasporic, resistant, or colonial).

The Study of Archaeology in North America

The study of North America's past is structured by the interaction and power relationships between academic institutions, governmental agencies, legislation, descendant communities, landowners, and other stakeholders. Archaeology – broadly defined as the study of cultural variation through material remains – is a relatively recent social science which was formalized only in the late nineteenth century (Trigger, 2006). As an organized academic discipline in North America, archaeology is most frequently considered a subfield of anthropology. In this respect, archaeology is closely affiliated with other branches of anthropology including linguistics, sociocultural anthropology, and biological anthropology. The integration of these subdisciplines is particularly strong in the United States due to institutional and governmental interactions with indigenous communities dating back to the nineteenth century. Academic archaeologists who specialize in classical civilization, medieval history, or Middle Eastern studies are often housed in other disciplines. The vast majority of North American archaeologists are not employed by academic units. In Canada and the United States, legislation has been enacted to preserve cultural resources. Although varying in particulars, scale, and applicability, these laws mandate that the adverse effects of ground-disturbing activities on lands owned or managed by national, provincial, local municipal, and tribal organizations should be mitigated (Neumann et al., 2010). Legislative tools for preservation fostered the development of a field of archaeology in the 1970s referred to as cultural resource management. Where required by law, private firms and public agencies are contracted to conduct surveys and excavations to determine the significance of cultural resources prior to development and conduct full-scale data recovery when significant cultural resources will be otherwise destroyed.

Although closely aligned with anthropology, what tends to differentiate archaeology is a methodological emphasis on the variation of human societies across space and through time. The archaeology of North America is traditionally parsed out into culture areas which correspond to major physiographic divisions. These include the Arctic and sub-Arctic in Canada and Alaska; the northeast in New England; the Mid-Atlantic of the eastern seaboard; the Southeast associated with the Ohio River Valley, the southern Coastal Plain and Florida; the Midwest along the upper and middle Mississippi River valley; the Plains from the state of Texas to the Canadian provinces of

Alberta, Manitoba, and Saskatchewan; the Rocky Mountains, the Southwest from the four corners to the Sonora desert; the Great Basin; Southern California; and the Northwest coast extending from Oregon into coastal Alaska. The particular boundaries of these regions will vary depending on the analyst and the criteria used to delineate them. The logic for separating these regions was first espoused by Bureau of American Ethnology archaeologist William H. Holmes in 1914, who noted that, at the time of sustained European contact, living cultures that were coincident with major ecological and climate zones (Holmes, 1914). These boundaries continue to be used as heuristic and organizing devices. However, they can be criticized for representing a snapshot of cultural variation that likely obscures the complex interactions and movements of communities across these arbitrary boundaries over the past 16 000 years.

With respect to time, a fundamental distinction is traditionally made between historic and prehistoric archaeology. In this system, historic archaeology investigates social process with the aid of written documentary sources. There are no known pre-European contact systems of writing documented in North America, and thus many would restrict historic archaeology to the past 500 or so years, spanning early European colonialism and later national expansion. With regards to prehistoric archaeology of unlettered cultures, a sequence of chronological periods is recognized in many regions based on changes in subsistence, settlement organization, social organization, and technological innovations. The Paleoindian period is associated with the earliest inhabitants of North America during the Pleistocene geological epoch (Walker and Driskell, 2007). This period witnessed the initial colonization of the continent and the establishment of hunter–gatherer economies that brought communities into close contact with megafauna. Although well represented in the interior, the Paleoindian coastal record is poorly understood due to subsequent sea-level rise. The succeeding Archaic period corresponds to the demise of most megafauna at the onset of the Holocene geological epoch. The Archaic was characterized by the development of increasingly diverse hunter–gatherer traditions. It was during the Archaic that many social, political, and technological institutions that had currency later in time were developed (Sassaman, 2004). These included the invention of pottery, the domestication of endemic plants or adoption of tropical cultigens, the construction of mortuary monuments, investment in land management through the construction of permanent facilities, and the differentiation of communities and perhaps individuals based on socioeconomic status.

Archaeologists working in some regions of North America recognize a Woodland period, characterized by an increased emphasis on ritual and ceremony, and in many locations a shift to a mixed subsistence strategy of foraging and cultivation (Anderson and Mainfort, 2002). The Late Prehistoric era corresponds to the establishment of politically complex societies organized around either chiefly elites who capitalized on the labor of others, or around federations of communities (Bayman, 2001; Blitz, 2010; Bamann et al., 1992; Moss, 2011). Attendant to political shifts in some regions were agricultural intensification of tropical cultigens such as maize, beans, and squash, and the investment in large public works. Within each region of study, further chronological subdivisions are recognized based on shared material culture, subsistence, and political organization.

Chronological boundaries for each period will vary based on local processes. Ultimately these periods are used by archaeologists to consolidate research questions. Yet these divisions can also be criticized for essentializing diverse lifeways using select criteria, or for promoting a unilineal model of social change from simple to complex (Alt, 2010). Further, a close inspection reveals that whereas agriculture was adopted by certain communities in North America, hunting and gathering persisted in many regions (notably the higher latitudes, the Plains, and the Pacific, Atlantic, and Gulf of Mexico coasts), often alongside agricultural communities. Using temporal divisions to categorize societies, it is possible to have 'Archaic' societies coexisting alongside 'Woodland' societies, for example Desert Archaic hunter–gatherers and Freemont farmers in the Great Basin (1400–600 years ago), or hunter–gatherers and agriculturalists inhabiting northern Florida (AD 1000).

Like other social sciences, archaeological explanation in North America has vacillated between historical or particularizing frameworks on one hand, and generalizing or evolutionary perspectives on the other (Trigger, 2006). The shift between either pole was frequently informed by empirical contradictions and broader social concerns. During the eighteenth and nineteenth centuries, inquiry was antiquarian in principle: explanation took the form of speculation or interest in objects for their own sake. The defining controversy that organized interest in North American archaeology at this time was the so-called 'myth of the mound builders.' When European colonists and their descendants expanded throughout the Eastern Woodlands they encountered landscapes saturated with earthen and shell mounds that often contained evidence for elaborate mortuary ritual. These works were seen in an ethnocentric light as evidence for 'advanced civilizations' who possessed economic, political, and cultural capabilities exceeding those of indigenous Native Americans and their ancestors (Squier and Davis, 1848). The controversy was settled in the late nineteenth century by extensive ethnohistoric research and archaeological excavations that linked contemporary indigenous communities with the archaeological record. This research was sponsored by the United States federal government and did much to formalize the asymmetrical relationships between descendant communities, government, the archaeological record, and academic institutions (Thomas, 1894). At this same time, generalizing evolutionary schemes were developed by the likes of Herbert Spencer and Louis Henry Morgan that explained contemporary human variation as a unilineal sequence of development from cultural and moral simplicity to complexity. Descriptions of living communities were often used as analogues of ancient communities, often with racist and ethnocentric overtones (Lubbock, 1865).

Stadial schemes were mostly abandoned following developments in sociocultural anthropology led by Franz Boas at the Columbia University in the early twentieth century. North American archaeologists rejected unilineal evolution and instead investigated the distinct and particular sequences of change evidenced in the archaeological record. The culture-historical approach emphasized stratigraphic methods for recording archaeological finds. By closely documenting where

objects were found within the site, archaeologists could track changes through time (Kidder, 1924). Patterns of change at a local spatial scale could then be compared with regional finds, and organized into space–time taxonomies (Willey and Phillips, 1958). Culture-historians operated with a normative view of culture, such that objects and archaeological sites represented the ideals or norms of particular groups. Past archaeological cultures were defined principally by lists of traits (such lists would include the type of settlement pattern, subsistence, technological style, and mortuary tradition) which were thought to represent social norms. The result was a static and pessimistic view of change.

The assumptions of culture-historical, or particularist, archaeology were challenged by processualism (the 'new archaeology') in the middle of the twentieth century. Processualism was predicated on a particular view of the archaeological record: the distribution of objects and places reflected dynamic processes in which humans adapted to their social and ecological environments (Binford, 1962). Processual archaeologists adopted a logical-positivist epistemology that foregrounded objectivism, scientific method, and a systems theory approach (*see* Archaeology: Philosophy and Science). Explanation involved using the archaeological record to test hypotheses, often derived from ethnographic or modern analogs. Archaeologists used the distribution and function of archaeological resources and independent variables such as population density or ecological structure to test hypotheses (Watson et al., 1971). Underwriting processual thought was a model of social evolution in which societies became increasingly complex through time (e.g., Service, 1962). Archaeological cultures were often classified into types (such as bands, tribes, chiefdoms, and states) that were reflected in subsistence economy, demography, and political organization. Popular research concerned hunter–gatherer variation, the circumstances of plant domestication, and the origins of complex society. Lewis Binford, for example, examined the subsistence, settlement, and social patterns of historic and contemporary hunter–gatherers in North America and elsewhere (Binford, 1990). He argued that social complexity in ancient times may have emerged in situations where high population densities and spatially restricted resources promoted reduced mobility and technological innovations to efficiently capture food.

Beginning in the late 1970s, the processual approach was criticized for ignoring the ideology of power and authority, and for a lack of concern with meaning. The critique was applied equally to interpretations of the past and to relations between archaeologists and indigenous communities whose cultural resources were investigated by archaeologists. Post-processual approaches foregrounded the significance of genders, embodiment, cultural traditions, cosmology, and identity in structuring the archaeological record (Brumfiel, 1992). There has been a rapprochement with history. Archaeologists are increasingly concerned with how cultural traditions are created as a historical process in which different groups (such as classes, ethnicities, genders) negotiate systems of value. Research also investigates the ways in which ancient communities created their own histories through social memory (Pauketat, 2001). Tradition making can be investigated by examining the history of how people created objects, and the ways in which objects and landscape use changed in the context of social interaction at local and regional spatial scales. Independent of post-processualism, a community of archaeologists applies insights from evolutionary theory to understand ancient change. In particular, so-called evolutionary archaeologists have focused on Darwinian natural selection and its influence on changes in social organization and technology through time (Dunnell, 1989). In this school of thought, cultural practices (memes) are subject to Darwinian natural selection and replication. Another school of thought argues that anatomically modern humans have evolved to be behaviorally flexible and economically rational (Boone and Smith, 1998).

In the past quarter century, archaeology in North America has become increasingly self-reflexive. That means that many archaeologists are now aware of the colonial history of the discipline, and how the production of knowledge is not inherently objective. This recognition is largely due to Native American and First Nation civil rights movements. These actions resulted in eventual federal legislation (NAGPRA in the United States) that provided a mechanism for protecting indigenous graves and repatriating cultural patrimony (Preucel and Cipola, 2008). Some archaeologists practice public archaeology, which considers the practical consequences and ethical realities of incorporating stakeholder communities. There are indigenous archaeologies conducted by First Nations and Native American communities as well (Pyburn, 2011). In decolonizing archaeological interpretation, opportunities are made for self-representation of historically marginalized groups. New kinds of narratives relating communities to the past are now possible in a variety of media, and are supported by inclusive national museums in Canada and the United States (Colwell-Chanthaphonh et al., 2011).

Contemporary Research Themes

Research into North America's 16 000 years of history is influenced by academic, social, and pragmatic concerns. That said, contemporary research can be grouped according to themes that cross-cut particular chronological or spatial boundaries or theoretical divides. The themes considered here include: (1) population movements, encounters, and the creation of new identities; (2) documenting the circumstances attending the materialization of myth and history in the landscape; and (3) detailing human–environmental relations with an eye toward informing contemporary and future practice in an age of global climate change. These themes will be discussed with reference to particular examples.

Encounters and Movement

North American archaeology is defined by the movement of populations, encounters of culturally diverse communities, and subsequent social transformations. Among these events, it would be hard to overstate the impact of European colonialism. Indigenous populations were decimated by disease. Those persons who remained were faced with reconstituting communities by either being incorporated into, or resisting, a world system that promoted cash economies over traditional social relations. Equally significant was the inclusion of Africans, who were traumatically removed from their natal communities. Archaeologists working with written and

archaeological records have explored the dimensions of power and alienation through which material culture, places, and landscapes were reconstituted among plural communities. Importantly, these studies have exposed how multifaceted and varied colonial experiences were depending on the cultural dispositions and strategic intentions of colonial powers. So too, gender relations among diasporic communities and indigenous cultures influenced how new societies were created. For example, in Spanish *La Florida* in the southeastern United States, Timucuan, Guale, and other groups were valued by colonial powers in terms of the labor they could provide for agricultural production. Missions were established throughout the region to convert persons to Christianity and suppress resistance to European authority. The presence of Native American pottery within otherwise Spanish households, however, indicates that native women were incorporated into Euro-American communities (Deagan, 2003). This situation suggests that native women were an important influence in the process of ethnogenesis (in which new ethnic identities and cultural traditions emerged from Indigenous and Euro-American practices). Similar processes may have occurred among Russian trading outposts such as Fort Ross in northern California (Lightfoot et al., 1998). In the frontier of southern California, in contrast, the initial relations between Spanish men and indigenous persons were likely through forced conscription or wage labor. Not until imperial demands on morality were loosened during the eighteenth century would gender relations and ethnogenesis be materialized in domestic foodways and architecture (Voss, 2008).

Archaeologists working in the Southeast have, since the 1960s, explored the archaeology of enslaved, diasporic communities at Spanish, British, and American plantations (Singleton, 1995). Despite the suppression of African identity by many plantation owners, some enslaved persons managed to maintain African foodways and traditions, at least in secret, or otherwise exercised resistance to oppression (Leone et al., 2005; Ruppel et al., 2003). Detailed historic observations provide the framework for reconstructing in digital form the structure of plantations or other prominent landscapes (such as Thomas Jefferson's Monticello). These spatial models provide a basis for reflection, and often reveal the inherent contradictions between landowners, others, and nationalist narratives. Beyond the immediacy of direct contact, archaeologists and ethnohistorians are now beginning to understand the effects of colonialism at increasing spatial scales. Although slavery is frequently assumed to have been directed at those of African descent, slave-raiding of Native Americans communities was conducted by Native Americans along a frontier expanding outward from the zones of initial contact in the seventeenth and eighteenth centuries (Ethridge, 2006). The archaeological implications are only now being tested, but appear to be manifested in differing community size, material culture assemblages, and patterns of group dispersion.

While the archaeology of migration and displaced communities traditionally has been the purview of historic archaeology, more recent research recognizes that disruptive processes associated with the movements of persons also occurred in the pre-Columbian era (Cobb, 2005). This work represents an important correction by acknowledging that although the particular circumstances of the modern world system did not exist in North America prior to European contact, there was no inherent schism between modern and pre-modern people. For example, some of the more elaborate architectural and symbolic florescences in Late Prehistoric North America – Chaco Canyon in the northern Southwest (AD 1000–1150) and Cahokia in the Mississippi American Bottom in the Midwest (AD 1050–1150) – appear related to migration and the politics of placemaking. Expansive landscapes composed of civic buildings for ritual performances (often with sacred and celestial alignments) were rapidly constructed in both regions. In the case of Cahokia there was the elaboration of place-specific material symbols, such as Ramey Incised Pottery and chunkee gaming stones, that were distributed throughout Cahokia's sphere of influence and evoked the power and religious authority of that place (Pauketat and Emerson, 2008). At Cahokia and Chaco Canyon there is evidence for intercommunity conflict and environmental fluctuations coincident with the emergence of these important places. Such regional processes may have instigated the abandonment of some regions and the aggregation of culturally disparate communities in others. Historically, however, the production of each of these localities by diverse communities occurred under the direction (and likely promotion) of the few (e.g., Cameron and Duff, 2008). The elevation of central places was likely an attempt by emerging elites to attain political and ideological dominance. Elites used contrasting practices of sponsoring inclusionary public ritual on one hand, but excluding the majority of people from direct access to specific ritual knowledge or symbols on the other. The archaeology of migrant villages, in particular in the farming villages surrounding Cahokia, highlights how these communities did not accept Cahokian authority without challenge. New kinds of community organization emerged as migrants incorporated traditional and new values into existing lifeways. The collapse of both Chaco and Cahokia reverberated through their respective regions as power structures were renegotiated locally. Communities once again engaged in movement away from former power centers.

The example of North America's first-millennium societies highlights the political and symbolic aspects of migration in groups that were politically and economically ranked. However, migrations into and throughout North America occurred at larger spatial and temporal scales, among smaller-scale communities several times in the ancient past. Indeed, one of the defining questions in the study of North American archaeology is: who were the first Americans? Before 1924, it was assumed that Native Americans had entered the continent only a few thousand years prior to European contact, the so-called short chronology. All that changed with the discovery of a stone tool in association with a now-extinct species of bison at the Folsom site in New Mexico (Meltzer et al., 2002). In the decades since, a new model emerged based on the discovery of a characteristic projectile point found across much of North America south of the ice sheets, and often associated with mammoth and mastodon remains. Referred to as 'Clovis,' this archaeological culture was widely accepted as the first to inhabit North America. Recent discoveries of coeval, but distinctly non-Clovis lifeways, such as at the Paisley Caves in Oregon (Jenkins et al., 2012), or even chronologically earlier communities, have led to renewed discussion about who the

first Americans were, and how they got to North America (Meltzer, 2009). This discussion will no doubt continue. Regardless, non-Clovis or earlier traditions open up the real possibility of multiple migrations, by numerous pathways along the coasts and interiors. These multiple migrations imply that there were many moments of culture contact at the dawn of human occupation of the region. Archaeologists, often working with the aid of historical linguists, have identified at least two other pre-Columbian migrations into North America out of the western Subarctic and Arctic. These include the Athapascan migration, which resulted in the emplacement of ancestral Apache and Navajo groups in the Southwest during the fourteenth century AD, and the Thule migrations across the Subarctic, which resulted in the displacement of earlier Paleo-eskimo communities (Friesen, 2004; Seymour, 2012). The historical processes attendant to these migrations are poorly understood. In the case of the Subarctic, migrations appear to have involved competition and negotiation with between migrants and indigenous communities (Holly, 2005).

Materializing Social Complexities Through Ritual

One area in which the archaeology of North America is broadly relevant to global social scientific research is in documenting and problematizing diversity and apparent complexity of recent and ancient hunter–gatherer communities. Before the 1970s, it was thought that pre-Columbian hunter–gatherers were, by default, characterized by low population densities, high residential mobility, and limited differences in social status or rank. Because environmental processes were considered determinant of social variation, considerably little attention was paid to the ways in which ritual, religion, and social negotiations structured hunter–gatherer lifeways. This model contrasted with historic evidence in several portions of North America for large, semi-sedentary hunter–gatherer populations that engaged in widespread landscape modification and participated in elaborate exchange and ritual. Most notable are the communities of the Northwest Coast of the United States and Canada, the Ohlone of the San Francisco Bay, the Chumash of southern California, and the Calusa of southwest Florida (Arnold, 2001; Lightfoot and Parrish, 2009; Moss, 2011; Widmer, 1988). Although variable in customs and politics, one shared feature was subsistence economies grounded in naturally occurring abundant aquatic and terrestrial resources.

In the decades since these so-called complex hunter–gatherers were recognized historically, a number of apparently similar examples have been documented in antiquity. The majority lived in the Midwest and Midsouth where riverine or coastal resources were intensively exploited during the Archaic period. One materialization of these subsistence economies are mounds of earth or shell, in addition to wide-ranging exchange networks of raw materials and finished objects. The extent to which these traditions represent complex societies in an economic sense has been a source of significant debate (Gibson and Carr, 2004). Traditional models for social complexity, grounded in institutionalized status distinctions based on material wealth, have failed to explain archaeological patterning. The analysis of grave inclusions fails to discern status distinctions beyond gender or age. A further point of debate regards the social significance of mounds of earth and shell. Since the resolution of the moundbuilder debate, the construction of monuments has been coupled with other cultural traits such as agriculture or pottery production. It was once thought that North American communities lacked the labor, politics, and worldview to construct such places until the Woodland period. Archaic mounds are problematic in that they are chronologically early, and in many cases composed of apparently mundane materials. However, a consideration of the history of these places suggests that many were purposefully constructed as integrative ritual facilities that may have promoted the inclusion of diverse persons from disparate regions (Sassaman, 2010). For example, the Archaic freshwater shell mounds of the St. Johns River in Florida were constructed for a variety of purposes. Some were residential in nature, but others including the 6300-year-old Harris Creek site, were dedicated mortuary mounds that were constructed for communal or individual burial, and others were ceremonial mounds constructed during ritualized aggregations. When viewed in historical terms, the movement between and modification of shell sites generated a complex social landscape supported by riverine resource exploitation, but justified by ritual practice. Similar processes of ritual incorporation and situational leadership, but at a much larger scale, were likely behind the construction of North America's second largest mound center, Poverty Point in Louisiana (Ortmann and Kidder, 2013). In this case, elaborate earthworks were rapidly constructed. The largest, the 22-m high Mound A, may have been constructed in as few as 3 months by 12 000 or more individuals drawn from regional communities, perhaps from throughout the Midwest and Southeast.

Human–Environment Relations

North American archaeology is characterized by a deep-seated interest in the relations between the environment and human social and historical variation. This focus has a long history in prehistoric archaeological thought in general (dating back to at least the eighteenth century), but has been particularly prominent in North American theory and practice. Earlier approaches have been criticized for emphasizing the role of the environment in structuring the long-term histories and decisions of ancient North Americans. At best, such environmental approaches assume that the environment significantly influenced long-term trends in population density and social organization. At worst, they reflect a deep-seated pessimism regarding the capabilities of small-scale societies to innovate solutions to environmental concerns. Theory aside, the emphasis on environmental histories is uniquely suited to address timely questions regarding human actions in the world, cultural dispositions, and climate change (anthropogenic or not) (Dawdy, 2009). North American archaeologists have developed innovative methods for recovering and interpreting evidence of past resource exploitation and landscape modification. These methods include paleoethnobotany and zooarchaeology (the study of past uses of plants and animals, respectively), geoarchaeology (the application of geological techniques to define the initial state of an archaeological site and the effects of time on that deposit), and a host of specialized techniques for recovering paleoclimatic data that have been adopted from environmental sciences.

Environmental archaeology has helped reveal the scale at which pre-Columbian communities were involved in managing and transforming physical landscapes. In most of North America, localized fire was used to encourage mosaic environments that fostered niches for edge-browsing game and fowl. In California, hunter–gatherer communities created fire-managed landscapes of high diversity that provided subsistence, medicine, and raw material, and supported the high population densities noted by the Spanish (Lightfoot and Parrish, 2009). North America also provides multiple models of plant domestication and social transformation. Tropical cultigens such as maize were initially domesticated in Mesoamerica (*see* Food Production, Origins of and Mesoamerica, Archaeology of). The pace and mode of adoption was variable across North America. As documented at the Las Capas site in the Tucson basin of Arizona (3200 years ago), early agriculture was enabled by social transformations and technological innovations such as water control via canal construction (Mabry and Davis, 2008). By way of contrast, maize arrived relatively late in New England (after AD 1000), but when adopted appears to have been incorporated into managed landscapes (Chilton, 2008). In the Midwest and Southeast maize was present by perhaps 2000 years ago, but was not important until the rise of complex polities thousand years later. Part of the resistance to maize was likely the land use practices associated with plants domesticated in North America. The so-called eastern agricultural complex included several plant species, most notably goosefoot (*Chenopodium* sp.), sumpweed (*Iva annua*), little barley (*Hordeum pusillum*), erect knotweed (*Polygonum erectum*), maygrass (*Phalaris caroliniana*), and sunflower (*Helianthus annuus*). These plants were intensively collected during the Archaic and fully domesticated by the Woodland period (Smith, 1989).

The social circumstances attending the transition toward cultivation remain poorly understood, but may relate to changes in ritual politics and feasting, together with less predictable climate. Ancient communities managed landscapes in less obvious ways. For example, Plains bison hunters created extensive landscapes through the construction of drive lines and other features. These systems enabled repeated bison kills at jump sites such as Head-Smashed-In in Alberta, Canada (Brink, 2008). In other cases, rock art in regions created sacred ties with landscapes, and likely aided in long-term management decisions with respect to traditional ecological knowledge. Ancient management undermines claims that pre-Columbian North America was a wilderness and provides a baseline for reconsidering the vulnerability of contemporary land use practices. In a similar vein, large-scale climate process that will likely affect North America in the decades to come – such as droughts, floods, and sea-level change – have already been experienced by ancient North Americans. The long history of developing traditional ecological knowledge with respect to landscape-scale rhythms will no doubt be a crucial resource for future managers and planners (Reo and Parker, 2013).

North American Archaeology in Context

The archaeology of North America is the product of communities of diverse cultural dispositions and worldviews negotiating social and ecological environments. Of equal importance is the history of investigations of these cultural resources, which have framed the significance of social practices identified in the past as much as the representations for various stakeholders. Although it is the 'past,' the archaeology of North America has much to contribute to contemporary and future concerns with climate change and the reconstitution of communities.

Abstract

The United States and Canada have long been understood through analysis of the sociocultural aspects of both everyday life and structural forces. Historical transformations in North America have spurred the development of social scientific theory about cultural difference, its sources, and its implications. Several ways of accounting for sociocultural life in the United States and Canada have been salient: as nations of local communities, racially organized societies, nations of immigrants, capitalist economies, contradictory democracies, and, increasingly, as settler colonial societies.

Research on the sociocultural aspects of North America (here focused on the United States and, secondarily, Canada; Mexico is discussed in a separate article) has produced a wide-ranging ethnographic record that centers on a core question: What kinds of societies and polities are the United States and Canada, and to what extent does the answer lie with cultural difference? Answers have transformed along with historical conditions that include post-Cold War global political reorganization, changing structures of economic life and resulting shifts in immigration and gender patterns, welfare state shrinkage, and the persistent inequalities and diverse lived experiences along lines that include race and gender. Many of anthropology's core theoretical and empirical concerns have been developed through the ethnography and ethnology of American lands, peoples, and polities. Anthropologists and other social scientists usefully have analyzed American societies and polities as: collections of local communities; a racialized former slave state; nations of immigrants; capitalist dreams or nightmares; and contradictory democracies. By the late 1900s, they demonstrated that sociocultural life in the United States is organized by kinship, gender, and sexuality. Increasingly in the early 2000s, scholars analyzed the connections among indigenous and nonindigenous North Americans by pointing out the ways that Canada and the United States operate as settler colonial societies.

Theorizing Human Difference from North America

North American cultural lives and social organizations have inspired prominent theories of human difference in anthropology. This is in part because of the region's evident diversity and, relatedly, an outcome of its colonial projects. Three examples illustrate the importance of sociocultural conditions in North America to the development of anthropological theory and, more broadly, of concepts that inform public understandings of human difference. First, during the mid-1800s, at a time when the United States and Canada were consolidating nationhood and progress narratives, the influential early anthropologist Lewis Henry Morgan studied Haudenosaunee society and therefrom developed an influential general theory of the stages of social development. His theory informed Engels and Marx and contributed to the rise of social evolutionism. Second, in the early twentieth century, as scientific racism consolidated and immigration boomed, Franz Boas built from American research (with indigenous peoples and immigrants, in particular) to develop his discipline-defining theory of culture as a nonreductionist explanation for human difference. Third, in the mid-1900s, as Cold War in America debated the role of material conditions in shaping culture, Julian Steward built his theory of cultural ecology from research on the relationship between environment and sociocultural life among indigenous peoples in the Great Basin. Although the paradigmatic object of anthropological analysis has been a distant cultural other, anthropologies of – not simply in – North America long have structured the discipline's core theories.

As is often observed, much of the anthropology of North America that focuses on indigenous peoples has been undertaken in a salvage mode (i.e., as if indigenous peoples as such were about to disappear), with Native American and Aboriginal peoples understood to be culture bearers appropriate for anthropological study. Research has gone hand-in-hand with colonialism, within North America and abroad. Meanwhile, as Lee Baker (2010) argues, anthropologists often viewed other North American groups and formations – he draws a contrast with African-Americans – less as cultural groups and, therefore, as less appropriate for anthropological study. The settler colonial structure of American life, as discussed below, organizes knowledge. That said, there is an old and deep anthropological literature about non-Native communities: in fact, US-based anthropologists study the United States more than any other region.

Communities of Difference

Many Americans understand the United States to be a nation that is comprised of local 'communities.' An emphasis on community has facilitated ethnographic methods of close engagement with the everyday lives of Americans, and it has afforded insights into lived diversity. Critical community studies have reckoned with the powerful American ideology of community that merges communitarian with localist/federalist traditions. Especially in the mid-1900s, ethnographers studied communities that they took to represent a fundamentally

American way of life. Lynd and Lynd's 1929 study of 'Middletown' and Warner's of 1930s 'Yankee City' (condensed in Warner, 1963), for example, showed how people refracted paradigmatically American values of individualism and hard work through community dynamics that often produced social difference and stratification. Community studies of American culture, as such, most often have been situated in white neighborhoods and towns: whiteness is the unmarked racial category in North America. Similarly, as Di Leonardo (1998) argued, anthropological studies that attempt to show 'America' to be just as exotic as any other society have taken middle-class, white-majority communities as their starting point.

Community studies of poor neighborhoods revealed how inequality permeates everything from the experience of unemployment and youth in Boston (Whyte, 1943) to the everyday rhythms of drug use and commerce in New York City (Bourgois, 1995). 'Culture of poverty' theories, which asserted that cultural dynamics produced dysfunctional family forms and hindered individual and group mobility, gained policy traction amidst 1960s civil rights struggles. The most famous example was the then-Assistant Secretary of Labor Daniel Patrick Moynihan's report on 'The Negro Family: The Case For National Action,' which identified African-American family structure and gender as legacies of slavery and Jim Crow segregation that contributed to dysfunctional 'ghetto' life. An ethnographic rejoinder, Stack's 1974 study of kinship and friendship recast poor African-Americans' social organization as robust in the face of structural inequality. Late-twentieth-century policy debates and scholarship often deployed the term 'culture' as a power-evasive euphemism for race. This uptake of the quintessentially anthropological term *culture* contravened the Boasian legacy of dissociating the two concepts (see below).

Community is not self-evident in North American social life: instead, the very idea of community has afforded Americans a resource for organizing belonging, difference, and politics. As Gregory (1998: 11) showed in his study of political culture and activism in an African-American neighborhood of New York City, "community describes not a static, place-based social collective but the power-laden field of social relations whose meanings, structures, and frontiers are continually produced, contested, and reworked in relation to a complex range of sociopolitical attachments and antagonisms." Similar approaches have reinvigorated regional analysis. In her study of the poetics of place and region in Appalachia, which often symbolizes rural poverty in scholarship and public culture, Stewart (1996) interrogates space and its narration as process and possibility. Weston's 1991 ethnography showed how gay and lesbian family transformed American kinship and its theorization by highlighting how kinship is built from community, as it is variously understood and produced. Community studies have both contributed to and disrupted common understandings of the United States as a tapestry of localized sociocultural groups.

Racially Stratified Societies, a Former Slave State

North America is fundamentally shaped by the sociocultural parameters, experiences, and consequences of race. In the United States, the nation-shaping institution of slavery and the ongoing inequality of African-Americans call into question dominant American narratives of freedom and equality, and the distinctive forms of racialization experienced by this and other groups illuminates the complexity and salience of race in everyday life. Anthropology established – through efforts to map sociocultural difference onto racialized biological difference – and then struggled to dismantle Social Darwinist understandings of race. The influential anthropologist Franz Boas's early 1900s theories of race informed both American public culture and also the most important US civil rights judicial opinions and legislation of the twentieth century. Boas's research on the cranial size of racialized second-generation Americans showed that the physical differences that scientists often had attributed race (and then used to explain differences in culture and intelligence) were mutable.

Baker (2010) contends that twentieth-century scholars generally associated questions of race with African-Americans and those of culture with, especially, Native Americans. This, in turn, contributed to a broader devaluation of African-American cultural distinctiveness, despite Hurston's (1990(1935)) and others' portrayal of the complexity of African-American cultural life. Increasingly, as the disciplines of sociology and anthropology separated in the mid-1900s, sociologists addressed African-American life while anthropologists dominated the study of Native American life: the latter rarely was theorized in terms of political status or race, but instead as cultural. This cultural framing of Native America remains the case even though Blu (2001(1980)), among others, has shown how blood and race structure indigeneity as a political category in the United States. Other contrasts warrant remark. For example, Drake and Cayton's Works Progress Administration-organized 1945 landmark study of Chicago's 'black metropolis' emphasized that African-American neighborhoods, by contrast with models of urban immigrant ethnic succession, sustained community structures that had been developed in the face of ongoing barriers to economic and geographical mobility. With the rise of Ethnic Studies and post-Civil Rights debates about race, and as demographers predict that by the mid-2000s whites will comprise a minority of the population of the United States and that 'visible minorities' will comprise one-third of the population of Canada, Frankenberg (1993) and others examined the sociocultural contours of whiteness, including at its intersection with gender.

The sociocultural aspects of race in America are lived at the level of everyday experience. From conspiracy theories to DNA ancestry testing to hip-hop, Jackson (2005) shows how turn of the century African-Americans and their interlocutors mobilized race toward intersubjective evaluation and interconnection. As Greenhouse (2011) argued, many community studies in the late twentieth century debunked racial stereotypes but eschewed direct engagement with related policy debates (e.g., 1990s racially punitive federal welfare reform policies that dismantled public benefits and exemplified welfare state retrenchment). Overall, despite trenchant research, and even as anthropologists teach in classrooms that race is a social construction rather than a biological trait, anthropological research on race in North America has lagged by comparison to insights from sociology, history, and interdisciplinary ethnic and American studies.

Nations of Immigrants

That the United States and Canada are 'nations of immigrants' has been variously presumed and investigated. Following the (anthropologically engaged) early twentieth-century Chicago School of Sociology's ethnographic examination of 'ethnic succession' and acculturation in urban neighborhoods, anthropologists have attended to the ways that immigrants are slotted into American structures of difference and inequality. By the late twentieth century, research findings and debates over multiculturalism, along with the ongoing conversation about Quebec's status in Canada, challenged the assumption that becoming American meant the gradual adoption of (implicitly white Anglo) dominant American sociocultural forms of life. Instead of experiencing a universal path, immigrants differentially become racialized into unequal forms of citizenship. For example, Ong's complementary books on the 'flexible citizenship' of East Asian transnational elites in Canada and the United States (1999), on the one hand, and the stigmatized citizenship of low-income Cambodian refugees in California (2003), on the other hand, showed that becoming American in the late twentieth century came with distinct trajectories for different groups.

Research through the twentieth century, therefore, shifted from proving immigrants' equality by showing their capacity for assimilation to charting the ways that immigration structures subjectivity and inequality. Migration is a cultural process that often includes the everyday experience of (il)legality and deportability, as Coutin (2000) showed for Salvadoran migrants to California and De Genova (2005) for 'Mexican Chicago.' These and other ethnographies of the growing Latin American migration to the United States adopted a transnational perspective and thereby challenged the older assumption that migration was a one-way cultural journey. American cultural life changes and becomes all the more globally connected as a consequence of migration. Kinship, gender, and sexuality shape these patterns and experiences, as Manalansan (2003) demonstrated for Filipino gay men. If the United States and Canada are (in part) nations of immigrants, these are stratified and unruly migrations that continually prompt national debates about the meaning and qualities of citizenship.

Capitalist Economies

In scholarship and public debate, the United States has been viewed as an exemplar of capitalism, for better or worse, and both the United States and Canada are characterized by the contradictions of capitalism and inequality. From Goldschmidt's (1947) criticism of corporate agriculture's erosion of community to Nash's (1993) examination of the relationship between community and capitalist industry to Sacks's (1988) ethnography of health care worker rights struggles, research has shown economic organization – and, more specifically, the logics of capitalism – to permeate American social and cultural life. Studies of work by Chicana (Zavella, 1987) and immigrant women (Lamphere, 1987), among others, have revealed how gendered family forms and racial/ethnic subordination are produced and reinforced by market structures. These market structures are shaped by political processes, as poverty is produced and lived through neoliberal policy and economic restructuring (see, e.g., the approach to poverty studies in Goode and Maskovsky, 2001).

Capitalism affects sociocultural life through the direct effects of day-to-day work, the economic organization of communities, and the everyday experience of economic inequality, opportunity, and community in a class-structured society. Ortner (2003), for example, showed how class shaped the life course of her high school classmates from New Jersey. Chin's (2001) ethnography of how African-American children purchase and use dolls and other objects demonstrates that consumption structures not only class but also race and other social formations. Capitalism also structures American sociocultural transformation, the mundane desires and interactions of American people, and the circulation of cultural forms such as film and music (see, e.g., Ortner, 2013, on independent films).

Anthropological methods and ethics long have privileged research in which the scholar develops sympathy with – and sometimes advocacy for – research participants. Acknowledging that such an approach systematically produces research on power's effects rather than on its production, ethnographers have studied economic elites, power brokers, and others at the center of power. For example, ethnography of Wall Street (Ho, 2009) reveals the institutional practices by which inequality is perpetuated at local and global scales. 'The market,' such research shows, is neither an abstract force nor an acultural collection of individual and institutional actors: rather, markets are sites wherein people learn and propagate values through observable sociocultural processes.

Increasingly, American economic life and its sociocultural dimensions are studied as transnational processes: for example, the authors in Maskovsky and Susser (2009) view domestic policy as the home front of American empire, with empire always comingling political and economic projects. That is, global capitalism is not simply an extension of American power and values into far-flung corners of the globe. Instead, it is a force that is produced, extended, and transformed in part through transnational sociocultural processes that also transform life in North America.

Contradictory Democracies

US- and Canadian-style democracies are forms of political organization that emerge from – and, in turn, shape – social and cultural formations. Alexis de Tocqueville wrote about the ways that 1830s Americans' everyday values dovetailed with their democratic order, Jackson Turner advanced his 1893 'frontier thesis' that associated masculinist American spirit with colonial expansion, and American political discourse long has associated democracy with individual and group characteristics. Masco (2006) views the US as a Cold War state (exemplified by Los Alamos), with Cold War logics shot through science, human and nonhuman life forms, and Americans' psychological dispositions. The idea that the United States is 'exceptional' – as a nation founded in democracy and committed to the nonimperial spread of liberty – has been

roundly criticized by critics of American imperialism and settler colonialism.

As they do elsewhere, legal anthropologists of North America deploy the methods of ethnography and sociolinguistics to understand how legal processes take hold in everyday life. They show how court claimants understand justice, immigrants tackle the bureaucratic hurdles of authorization, or courtroom actors encode cultural values in speech and evidentiary standards. Law and policy changes at federal and state levels can have profound impacts on American lives, effects that too often go unseen in the social sciences. Ethnographic investigation of the consequences of 1990s welfare reform laws that transformed the role of work in access to state benefits, for example, called attention to the struggles of Americans to undertake social reproduction in a new policy context. In Canada, as Mackey (1999) has shown, state multiculturalist policy buttresses Canadian narratives of being a tolerant democracy while simultaneously ossifying the cultural criteria by which claims for tolerance can be made. Anthropologists have played a role in implementing federal policy, including as researchers and administrators at World War II-era Japanese internment camps.

Cultural commitments congeal and transform through social movements and the politics of knowledge. For example, Ginsburg (1989) deployed ethnographic methods to show how the two sides of an abortion debate in North Dakota drew different conclusions from their shared view that women are harmed by the systematic separation of wage labor from domestic life and reproduction. Rapp (1999) vividly presented the ethics and sociocultural impact of amniocentesis and thereby highlighted the everyday politics of knowledge production and dissemination.

Anthropologists have asked how the paradigmatic disciplinary concept of 'culture' itself becomes (or always already is) political in North America. Handler's study of cultural patrimony in Québec shows nationalism to be forged through the claim to 'having a culture.' More generally, cultural claims to political belonging are unevenly distributed across race, class, gender, and other forms of difference. Rosaldo (1997) and other theorists of 'cultural citizenship,' for example, observe that people of color build civic claims and experiences from positions of racialized and cultural difference. As with immigration (discussed above) and the contradictions of democratic life more generally, anthropologists have shown citizenship in the United States and Canada to be as much about everyday belonging and exclusion as about formal legal status.

Settler Colonial Societies

In this volume, as in many, research about the United States is categorized as largely distinct from that about American Indian nations. This does not generally result from a stated commitment to underlining indigenous sovereignty and the political distinctiveness of Native nations. To the contrary, Native peoples in the United States long have been studied in anthropology, but review articles and course offerings within the discipline more often than not treat Native America as a distinct 'culture area.' This scholarly tradition reproduces a broader US public culture in which indigenous peoples more commonly are associated with past tradition (or present-day socioeconomic failure and cultural decline) than with a vibrant and contradictory American present or future. In Canada, indigeneity joins Québec's status as a prominent topic in political theory, not only in anthropology. First Nations, Inuit, and Métis peoples more frequently are understood in scholarship and public culture to form a constitutive part of the Canadian political order, albeit not necessarily on the terms or with the projected future that Aboriginal peoples choose.

The United States and Canada are settler societies with ongoing settler colonial relations among indigenous and nonindigenous peoples. Settler colonialism describes myriad sociocultural and political-economic formations that typify liberal democratic white-majority societies with dispossessed indigenous minorities. These include legal systems that recognize multiple sovereigns, struggles over how to encode differentiated forms of citizenship alongside a liberal democratic commitment to equal citizenship, the appropriation of indigenous culture for settler-state national patrimony and identity, a public culture and scholarly tradition that relegates indigenous authenticity and power to the past, and the association of indigenous peoples with poverty and precapitalism as against settler modernity. Wolfe (1999) shows how anthropological research contributed to settler colonialism's eliminatory logics. Classic settler colonial societies stemming from the British common law tradition are the United States, Canada, Australia, and New Zealand; not coincidentally, those were the four major states that voted against (and subsequently became the last to support) the 2007 United Nations Declaration on the Rights of Indigenous Peoples.

Settler colonialism creates a set of structures, practices, ideological formations, and dilemmas that are open to social scientific analysis. Relative to analysts in other disciplines, for example, anthropologists are likely to study indigenous sovereignty's local manifestations in everyday life. Cattelino's (2008) study of tribal gaming showed Florida Seminole sovereignty to be enacted through the coproduction of economic power with cultural and political distinctiveness. Relative to other anthropologists of sovereignty who more commonly focus on the sovereign's power to harm, those who study indigenous sovereignties call attention to sovereignty's political capaciousness (see, e.g., Sturm, 2002, on Cherokee blood and citizenship politics and Kauanui, 2008, on Hawaiian genealogy and political belonging). Such a focus on indigenous sovereignties, in turn, illuminates settler-state sovereignty. For example, Simpson (2014) examines Mohawk narratives of, and embodied practices at, the US–Canadian border to show how indigenous nationalism unsettles settler-state sovereignty.

Settler colonialism, and particularly the related presumption that indigenous peoples are disappearing, has shaped research on the sociocultural characteristics of the United States and Canada. The specter of indigenous disappearance that built four-field American-style anthropology in the nineteenth century formed part of broader US debates about modernity, American exceptionalism, and democracy. Documentation of indigenous culture at the turn of the twentieth century, often funded by national institutions such as the federal Bureau of American Ethnology, went hand-in-hand with the establishment of national(ist) patrimony in a still-young settler nation

that remained unsure of its pedigree. Late-twentieth-century ethical and methodological debates over disciplinary anthropology's relationship with Native America went to the heart of how knowledge production has been complicit in the dispossession of indigenous political and economic power. Cruikshank's (2005) ethnography of glaciers and colonial encounters at the border of British Columbia, the Yukon Territory, and Alaska told how social and biophysical processes combine to produce knowledge. When research with (or often on) indigenous peoples is understood to be about the settler nation more generally, it becomes clearer that anthropological research in and about the United States and Canada, as settler nations, is nothing new.

To describe the United States and Canada as settler societies foregrounds indigeneity as a constitutively dispossessed condition of American life for all of the continent's residents. Indeed, emergent inquiry into settler colonialism and the politics of indigeneity has the potential to account for the ways that being a settler society structures all American lives. Doing so does not obviate the value of describing North America in other ways – through the study of community, race, immigration, capitalism, democracy, and more – but, rather, joins with these in the effort to capture both the structural forces and lived experiences of these diverse lands and peoples.

Nosology in Psychiatry

This article is a revision of the previous edition article by R.E. Kendell, volume 16, pp. 10737–10744, © 2001, Elsevier Ltd.

Abstract

Nosology is a classification of disease in which disease categories are mutually exclusive and jointly exhaustive, and may also have other formal relationships to one another as well as being arranged either in tiers or in a hierarchy. The most influential classification systems in contemporary psychiatry are the World Health Organization's *International Classification of Diseases – 10th edition* (ICD-10) and the American Psychiatric Association's *Diagnostic and Statistical Manual – 5th edition* (DSM-5). These classification systems have converged over the years but are still distinct documents. This article reviews the historical aspects of the development of nosology and classification systems in psychiatry from the Classical Greek period to the modern day. It emphasizes the strength of contemporary nosologies, namely, the marked improvement in reliability that is due almost entirely to the development of formal diagnostic criteria and guidelines. The most obvious weakness of both contemporary nosologies is the limited evidence for the validity of most of their constituent categories. The combination of a limited understanding of the etiology of most mental disorders and the lack of evidence for natural boundaries or 'zones of rarity' separating their clinical syndromes means that most existing diagnostic concepts and definitions are not securely based.

Although mental disorders have figured in nosologies since Hippocrates, separate classifications of mental disorders did not appear until the nineteenth century. For a long time, confusion reigned and early attempts to secure agreement on a single international classification ended in failure. When it became clear to the World Health Organization (WHO) in the 1950s that few countries were using the International Classification of Diseases (*ICD-6*) which they had themselves formally approved, a concerted attempt was made both to improve the mental disorders section of the *ICD* and to persuade everyone to use it. Despite a widespread disenchantment with diagnoses, *ICD-8*, published in 1965, was a better and more widely used nosology than its predecessors, but the WHO lacked the political power to make major changes. The classification produced by the American Psychiatric Association in 1980 (*DSM-III*) provided these radical changes – multiple axes, operational definitions, a new grouping of syndromes, and rejection of several ancient terms. All subsequent nosologies, including the *ICD*, have incorporated most of these. At present, two nosologies are in widespread use – The American Psychiatric Association's *DSM-V* and the WHO's *ICD-10*. Although operational definitions of syndromes have greatly improved reliability, the validity of most diagnostic concepts is still uncertain and this is only likely to change with better understanding of etiology.

Nosology is the classification of diseases (from the Greek words *nosos*, disease, and *logos*, discourse), whereas taxonomy is the classification of animals or plants. A nomenclature is simply an approved list of categories or titles. In order to constitute a classification, its categories must be mutually exclusive and jointly exhaustive, and may have other formal relationships to one another as well, being arranged either in tiers or in a hierarchy.

History: From Hippocrates to the 1940s

For at least the last 2500 years, most generations of physicians and several philosophers have produced a nosology. Usually this was not because they were preoccupied with classification. It was because a nosology almost inevitably reflects the range and variety of diseases recognized by its authors, the extent of their clinical experience, their assumptions or knowledge about etiology, and their familiarity with or ignorance of the detailed manifestations of illness. Nearly all these nosologies have incorporated several categories of what we now regard as mental disorder, thereby demonstrating that their authors regarded these disorders as diseases to be treated by physicians, and usually with the same range of assumptions about causation and treatment as other diseases.

It is apparent from the corpus of writings attributed to him that Hippocrates recognized at least six different forms of mental illness:

1. phrenitis (acute mental disturbance with fever),
2. mania (acute mental disturbance without fever),
3. melancholia (chronic mental disturbance),
4. epilepsy,
5. hysteria (convulsions and other paroxysmal symptoms), and
6. scythian disease (cultural transvestism).

His contemporary, Plato, on the other hand, distinguished between Natural Madness originating in physical disease and several kinds of Divine Madness (Prophetic Madness given by Apollo, Religious Madness given by Dionysus, Poetic Madness inspired by the Muses, and Erotic Madness inspired by Aphrodite and Eros).

Many of the nosologies developed over the next 2000 years are listed by Menninger (1963). Most were fairly simple and incorporated Hippocrates' categories of mania, melancholia, and epilepsy. Others, like those of Boissier de Sauvages and William Cullen at the end of the eighteenth century, contained several hundred categories of disease arranged in tiers mimicking the orders, genera, and species of plants. Only in the nineteenth century, with the emergence of physicians specializing in the treatment of insanity (known as alienists), did separate classifications of mental illness start to appear. They

quickly proliferated, however, because every self-respecting alienist, and certainly every professor, produced his own nosology, some based on behavioral differences, others on presumed differences in etiology, others on psychological differences, and some on a mixture of all three. Indeed, as a medical historian subsequently observed, "to produce a well-ordered classification almost seemed to have become the unspoken ambition of every psychiatrist of industry and promise."

It was soon apparent that this multiplicity of classifications, with diverse meanings often attributed to the same terms, rendered communication between one hospital and another almost impossible, and with this came recognition of the need for a single nosology acceptable to everyone. At the Congress of Mental Medicine in Antwerp in 1885, a commission was appointed, chaired by a Belgian alienist, Morel, to produce this. The commission duly delivered a simple typology that was adopted formally by the International Congress of Mental Science in Paris in 1989, but as the English psychiatrist, Hack Tuke, had predicted, its nosology was generally ignored. However, as this was the first formal attempt to secure international agreement and the forerunner of the present International Classification, its 11 categories of insanity have some historical significance. They were

1. mania,
2. melancholia,
3. periodical insanity (Baillarger's *folie a double forme*),
4. progressive systematic insanity,
5. dementia,
6. organic and senile dementia,
7. general paralysis,
8. insane neuroses (hysteria, epilepsy, hypochondriasis, etc.),
9. toxic insanity,
10. moral and impulsive insanity,
11. idiocy, etc.

While Morel and his colleagues were engaged on this ultimately fruitless task, several national organizations were pursuing similar but more modest aims. In Britain, the Royal Medico-Psychological Association (the forerunner of the Royal College of Psychiatrists) produced a classification in 1882, which it recommended to its members for general use. Further drafts were produced in 1904, 1905, and 1906 before the Association finally accepted that there was no prospect of persuading its members to restrict themselves to the diagnoses listed in any official nomenclature, British or international. A similar sequence of events took place in the USA. In 1886, the Association of Medical Superintendents of American Institutions for the Insane (the forerunner of the American Psychiatric Association) adopted a modified version of the British classification of 1882. This was revised in 1913 to incorporate Kraepelin's concepts of dementia praecox, involutional melancholia, and manic depressive insanity but, even so, many States and asylums still preferred to use their own nosologies, or declined to be bound by any nomenclature, national, or local. Indeed, the New York State Commission in Lunacy continued to use its own private classification until 1968. In 1937, the need for an internationally agreed nosology was discussed once more at the Second International Congress for Mental Hygiene. Although it soon became clear that there was still little hope of any real consensus emerging, the simple eight-category classification proposed by the French psychiatrist Bersot was adopted by two countries, Portugal and Switzerland, and remained in use in both the countries for 20 years.

The Origins of the World Health Organization's International Classification

Largely at the instigation of two medical statisticians, William Farr in London and Jacques Bertillon in Paris, the International Statistical Congress had, as far back as 1853, recognized the need for '*une nomenclature uniforme des causes de décès applicable a tout les pays*' (a uniform nomenclature of causes of death applicable to all countries) and had not only produced such a nomenclature but revised it regularly for the next 50 years. Probably because of the importance of mortality statistics to public health and to governments, these successive editions of what came to be known as the Bertillon Classification of Causes of Death were used increasingly widely; and in 1900, the French Government assumed responsibility for the classification and convened a series of international meetings in Paris in 1900, 1920, 1929, and 1938, and thereby produced four successive editions of what was by then called the International List of Causes of Death.

When the World Health Organization (WHO) came into being in 1948, one of its first public actions was to produce a sixth revision of this International List. Renamed the International Statistical Classification of Diseases, Injuries and Causes of Death (*ICD*), this was for the first time a comprehensive nosology covering the whole range of disease, rather than merely causes of death, and so for the first time included a classification of mental illness. In fact, Section The Third Edition of the American Psychiatric Association's Classification (DSM-III) of this sixth revision (*ICD-6*), entitled 'Mental, Psychoneurotic and Personality Disorders,' contained 10 categories of psychosis, nine of 'psychoneurosis,' and seven of 'disorders of character, behavior and intelligence,' most of them subdivided further. Unfortunately, although the nomenclature of *ICD-6* was adopted unanimously by the 1948 revision conference, and was duly 'recommended for use' by all the member states of the WHO, its mental disorders section failed to gain acceptance, and 11 years later, it was found to be in official use only in Finland, New Zealand, Peru, Thailand, and the UK. History was repeating itself. Deeply concerned by this state of affairs, the WHO commissioned an English psychiatrist, Erwin Stengel, to investigate the situation and if possible to make recommendations.

The situation that Stengel encountered he described as one of 'almost general dissatisfaction with the state of psychiatric classification, national and international' and the attitude of many psychiatrists toward the classification of mental disorders seemed to have become 'one of ambivalence, if not of cynicism' (Stengel, 1959). Many countries had official classifications of their own, some of recent origin, others dating back to the 1930s, but none, new or old, was regarded as satisfactory by its users, or used conscientiously and consistently by them. In the UK, although the General Register Office published mental hospital admission rates and other data in the format of the *ICD*, the returns from individual hospitals from which these

data were derived frequently showed a blatant disregard for, or ignorance of, the requirements of the nomenclature. In the USA, Section The Third Edition of the American Psychiatric Association's Classification (DSM-III) of the *ICD* was ignored completely, despite the fact that American psychiatrists had taken a prominent part in drafting it. Instead, a nosology drawn up by the American Psychiatric Association and published in 1952 as a *Diagnostic and Statistical Manual* (*DSM-I*) was in widespread use. Even so, there were serious local problems. The New York State Department of Mental Hygiene still insisted on retaining its own classification, and influential psychoanalysts like Menninger (1963) argued forcefully that classifying patients into categories of illness did more harm than good and should be abandoned.

Reasons for Dissatisfaction with Psychiatric Classification

Many factors contributed to the unwillingness of psychiatrists to commit themselves to using a common nosology and to the general dissatisfaction with all classifications. Most fundamentally, there was no rational criterion available to enable the psychiatric community, faced with the need to choose between several alternative nosologies, to decide which was the best, or most valid. In other branches of medicine, the old diagnostic concepts and nosologies inherited from the eighteenth century or before had largely been replaced by new concepts and classifications based on at least a partial understanding of etiology. Phthisis had been replaced by pulmonary tuberculosis, myxoedema by hypothyroidism, and Mediterranean anemia by thalassemia, and no physician doubted the validity of these new concepts or the value of classification. Psychiatry, on the other hand, remained as ignorant as ever about both the pathology and the underlying causes of most of its common disorders, and so was compelled to continue defining these disorders by their syndromes, just as Sydenham had done in the seventeenth century, and went on using ancient Hippocratic terms like mania and melancholia.

A further problem was that many of these disorders appeared to merge into one another. A few conditions, like Down's syndrome and Huntington's chorea, did seem to be clearly demarcated but most were not. Patients with the characteristic symptoms of one disorder not infrequently presented with the typical symptoms of a quite different disorder on a subsequent occasion, and it was a commonplace to encounter patients with a mixture of the characteristic symptoms of what were supposed to be unrelated disorders. Such problems bedevilled the distinction between, for example, schizophrenic and manic depressive psychoses, and between depressive illnesses and anxiety states, and resulted in either persistent controversies about how best to distinguish the disorders in question or, even worse, doubts about the validity or usefulness of the diagnoses themselves.

The combination of these two problems – the lack of understanding of etiology or of any demonstrable pathology, and the absence of obvious boundaries between several of the most common syndromes – meant that, in many instances, there was no rational means of choosing between alternative diagnostic concepts or alternative nosologies. In this situation, most psychiatrists, understandably, opted to use whichever diagnostic terms and whichever classification were most familiar, particularly if they were their own.

Other considerations also contributed to the problem. Few of the diagnostic terms in common use held important therapeutic implications. Before the 1960s, there were few treatments that were only effective in a single diagnostic category. Electroconvulsive therapy was effective in most acute psychoses – schizophrenic, melancholic, or manic. Chlorpromazine and the other new neuroleptic drugs appeared to have a similarly broad range of efficacy. Most influential of all, particularly in North America, was the fact that a diagnosis had ceased to be a necessary precondition to treatment, because psychoanalytically oriented psychotherapy was widely regarded as an effective and appropriate treatment across almost the whole range of psychiatric disorders from mild character disorders to florid schizophrenia. The implications of diagnoses for prognosis were equally tenuous. There were, to be sure, well-established differences in outcome between populations of patients with different diagnoses, both in the short and the long terms. On average, the course and outcome of schizophrenic and affective psychoses, or of depressions and anxiety states, were significantly different. But the overlap was very substantial, and as a result, a diagnosis was only of limited value in predicting outcome in individual patients. By the early 1960s, it was also becoming apparent that the reliability of psychiatric diagnoses, even those of experienced psychiatrists, was often alarmingly low, and that even under optimal conditions, disagreements were commonplace – because the patient gave different information to different interviewers or because that information was interpreted in different ways or because there were covert differences in the interviewers' diagnostic concepts.

Finally, many psychiatrists and psychologists were concerned about the harmful effects that diagnostic labels often had on their patients. Labels like hysteria or schizophrenia sometimes encouraged hospital staff to treat the patients in their care as 'hysterics' or 'schizophrenics' rather than as distressed people. Several diagnostic terms also had pejorative overtones, lowering the patient's self-esteem even further than their illness itself had already done and encouraging relations, neighbors, colleagues, and employers to belittle them.

The Response to These Problems

The most important recommendations in Stengel's report to the WHO were that all diagnoses should be explicitly shorn of their etiological implications and regarded simply as 'operational definitions' for specified types of abnormal behavior, and that the next revision of the *ICD* should have an accompanying glossary 'available from the beginning in as many languages as possible' providing a brief description, or thumbnail sketch, of all the disorders in its nomenclature. Other, mainly American, psychiatrists advocated operational definitions as a means of improving reliability. The problem with the brief descriptions Stengel was advocating was that, like traditional textbook descriptions, they described the typical features of a clinical syndrome without making it clear which combinations of those features were adequate to establish the

diagnosis in question. A typical textbook description, or the thumbnail sketch of a glossary, lists the typical symptoms of disease X as A, B, C, and D, and often goes on to say that E and F are sometimes present as well. But it does not spell out which combinations of those symptoms are adequate and which are not to establish diagnosis X, and as a result, different diagnosticians make different assumptions, and so often end up making different diagnoses. An operational definition is simply a statement, or a set of statements, which makes it clear for all possible combinations of A, B, C, D, E, and F, which are and are not adequate to establish diagnosis X.

The 1960s also saw the introduction of multiaxial classifications. The Swedish psychiatrist Essen-Moller had long advocated a classification with separate axes for symptomatology (i.e., the syndrome) and etiology, primarily as a means of resolving the difficulties that inevitably occur in a classification in which some disorders are defined by their symptoms (e.g., mania) while others by their presumed etiology (e.g., puerperal psychosis). As he pointed out, having separate axes would make it possible to identify all manic illnesses, whether or not they occurred shortly after childbirth, and all puerperal illnesses regardless of their symptomatology. Shortly afterward, a WHO working party – set up to produce some much needed recommendations for an improved classification of childhood disorders in the *ICD* – made a firm recommendation that a triaxial classification with separate axes for the clinical syndrome, the child's intellectual level and 'etiological and associated factors' should be tried out and, if these pilot studies proved successful, incorporated into the next revision of the *ICD*.

The Eighth and Ninth Revisions of the International Classification (ICD-8 and ICD-9)

Stengel's report and the recommendations of its own expert committee were taken seriously by the WHO, and the next (eighth) revision of the International Classification, which was published in 1965 and came into use in 1969, was a considerable improvement on its predecessors. For the first time, all psychiatric disorders were brought together in the Mental Disorders section of the classification, thus making it self-sufficient and easier to use. The sections dealing with personality disorders, sexual deviations, mental retardation, alcoholism, and drug addiction were all expanded and recast and a new group of reactive psychoses was introduced at the request of Scandinavian psychiatrists. Even more important, the American Psychiatric Association was persuaded, despite considerable domestic opposition, to commit itself to using the nomenclature of *ICD-8* instead of that of its own *Diagnostic and Statistical Manual*. The German and Scandinavian psychiatric societies also agreed to use the new nomenclature so that, for the first time, all the major contributors to the psychiatric literature, with the notable exception of France, were committed officially to using the same classification. Unfortunately, the committee responsible for producing the companion glossary that Stengel had so strongly recommended did not start work until 1967 and the glossary was not published until 1974. The hiatus was partly filled, though, by the publication in 1968 of two national glossaries – American and British – to the nomenclature of *ICD-8*.

The ninth revision (*ICD-9*) was published in 1978, and this time the companion glossary was available from the beginning. But despite a series of eight international seminars held between 1965 and 1972, attended by psychiatrists from over 40 countries, there were no major changes. A few new categories, like nondependent abuse of drugs, were added in recognition of the broadening scope of psychiatric practice, a clearer distinction (reminiscent of Plato's distinction between natural and divine madness) was drawn between organic psychoses and other psychoses, and there was a substantial expansion of the number of categories allocated to disorders of childhood, but that was all. None of the fundamental problems – like the low reliability of diagnostic assignments, the tensions created by the incorporation of etiological assumptions into diagnostic terms, and the increasingly complex and chaotic classification of depressions – had been tackled effectively. It was also clear why this was so. The need for international consensus – the agreement of nearly 200 sovereign states to use the same nomenclature – was making it almost impossible to introduce radical changes; and an increasing number of sometimes incompatible terms were being added to the nomenclature with each new revision, because individual psychiatric societies always fought for the inclusion of their own favorite terms more persistently than they were prepared to oppose the attempts of others to do likewise. It was becoming apparent, in other words, that if fundamental improvements were ever to be achieved, it was unrealistic to expect the WHO to be the driving force.

The Third Edition of the American Psychiatric Association's Classification (DSM-III)

For the research community, the most important shortcomings of all classifications of mental disorders, national and international, were the low reliability and uncertain validity of most of their diagnostic terms. The Washington University Department of Psychiatry in St Louis in the USA reacted to this situation by publishing what came to be known as the Feighner criteria – a set of operational definitions, intended for research use, of the 15 major syndromes they regarded as having been adequately validated (Feighner et al., 1972). Other rival sets of definitions, like the Research Diagnostic Criteria, soon followed, and in this climate, the American Psychiatric Association committed itself to producing a new, third edition of its *Diagnostic and Statistical Manual*. When it was finally published in 1980, this *DSM-III* was dramatically different from any previous nosology of mental disorders. It was multiaxial with independent recording systems for five different kinds of information – the clinical syndrome or syndromes; associated personality or developmental disorders; associated physical disorders; the severity of recent psychosocial stresses; and the highest level of social functioning in the past year. The grouping of clinical syndromes was also novel, with all affective disorders brought together and the traditional distinction between psychotic and neurotic disorders abandoned. Even more provocatively, many of the psychiatry's most hallowed terms – like hysteria, manic-depressive illness, and even psychosis and neurosis – were discarded and replaced by unfamiliar and rather unattractive terms like somatoform

disorder, substance use disorder, and paraphilia. A brave but only partially successful attempt was also made to define the term 'mental disorder.' Finally, and most important of all, nearly all the 200 categories of disorder in the manual were provided with operational definitions, and it was demonstrated in extensive field trials that this made it possible to achieve higher reliability than had ever been attained previously.

None of the innovative features of *DSM-III* was entirely novel. The advantages of both multiple axes and operational definitions had been pointed out long before and both had already been introduced into clinical practice in some centers. The concept of hysteria had been under attack for over a generation, as had the distinction between psychotic and neurotic disorders. What was new was that a powerful professional body like the American Psychiatric Association was prepared to commit itself and its members to all these innovations simultaneously. For a time the fate of *DSM-III* hung in the balance, for in the eyes of many older and still influential psychiatrists, its authors had gone too far. But before long, its advantages were increasingly apparent and eventually it became a best seller, in not only the USA but also worldwide.

With hindsight, the adoption of *DSM-III* was a crucial step in the development of a scientific nosology of mental disorders. Certainly, all subsequent nosologies – national and international – have been deeply influenced by it. Of all its innovative features, the commitment to operational definitions was the most important. Not only did this result in a major improvement in the reliability of psychiatric diagnoses and eliminate the unsuspected differences in diagnostic criteria that had previously bedevilled international comparisons, they also made it explicit that diagnostic terms like schizophrenia were simply convenient designations for more or less arbitrary groupings of symptoms.

Nosologies (1992–2013)

The Fourth Edition of the American Psychiatric Association's Classification (*DSM-IV*)

The American Psychiatric Association published a revision of *DSM-III* in 1987 and a new fourth edition (*DSM-IV*) in 1994. Neither abandoned any of the fundamental features of *DSM-III*. For the most part, they simply corrected the anomalies that had come to light, reworded several operational definitions in order to improve their reliability or to conform with changes in expert opinion, and introduced a few additional categories of disorder. A new 'clinical significance' criterion was also added to the definition of many disorders in *DSM-IV* to counter the criticism that too many people met with the *DSM-III* or *DSM-IIIR* criteria for common conditions like major depression and phobic disorder and that many of them were not significantly handicapped.

The authors of *DSM-IV* also endorsed and expanded the rather cumbersome *DSM-III* definition of 'mental disorder' as "a clinically significant behavioral or psychological syndrome or pattern that occurs in an individual and that is associated with present distress or disability or with a significantly increased risk of suffering death, pain, disability, or an important loss of freedom." In addition, it was stipulated that "this syndrome or pattern must not be merely an expectable and culturally sanctioned response to a particular event, for example, the loss of a loved one," and that "whatever its original cause, it must currently be considered a manifestation of a behavioral, psychological, or biological dysfunction in the individual," thereby emphasizing that "neither deviant behavior nor conflicts that are primarily between the individual and society are mental disorders unless the deviance or conflict is a symptom of a dysfunction in the individual." The introduction to *DSM-IV* also emphasized, rather more succinctly, that "the term mental disorder unfortunately implies a distinction between mental disorders and physical disorders that is a reductionistic anachronism of mind/body dualism. A compelling literature documents that there is much physical in mental disorders and much mental in physical disorders. The problem raised by the term mental disorders has been much clearer than its solution, and, unfortunately, the term persists in the title of *DSM-IV* because we have not found an appropriate substitute."

The Tenth Revision of the International Classification (*ICD-10*)

The WHO published a tenth revision of the *International Classification* in 1992, after extensive consultations and field trials in several different parts of the world. Although the titles and definitions of many of the disorders listed in the Mental and Behavioural Disorders section of this *ICD-10* are different from those of either *DSM-III* or *DSM-IV*, its debt to the former is obvious. The general format of the two nosologies is very similar and, crucially, *ICD-10* provides 'diagnostic criteria for research' for every category (i.e., operational definitions) as well as 'clinical descriptions and diagnostic guidelines' for ordinary clinical use (WHO, 1992, 1993). This was only possible because, by the time the member states of the WHO were called upon to endorse the draft text of *ICD-10*, there had been time for the international psychiatric community to come to terms with the radical innovations of *DSM-III* and to appreciate their advantages. Significantly, though, no attempt was made to define the term 'mental or behavioral disorder.' Indeed, there is an apologetic note in the introduction explaining that "the term disorder is used…so as to avoid even greater problems inherent in the use of terms such as disease and illness. Disorder is not an exact term, but it is used here to imply the existence of a clinically recognizable set of symptoms or behavior associated in most cases with distress and with interference of personal functions."

At present, we are at cross-roads as *DSM-V* has just been published and *ICD-10* is undergoing revision. The two nosologies of so-called 'mental disorders' are in widespread use. In their essentials, they are very similar to one another. In points of detail – particularly, the titles and subdivisions of individual syndromes and the detailed definitions of these disorders – they are often different. The American classification is used mainly in North America and by research-oriented psychiatrists further afield. The *International Classification* is used elsewhere, particularly in Europe and developing countries, and by all governments for their formal statistical returns to the WHO. In some ways, it is regrettable that there are now, and will be for the foreseeable future, these two rival nosologies. However, the confusion generated by two rivals is much less than that

produced by a dozen, the nightmare of the 1950s. There are also advantages in having some choice. The coexistence of alternative titles, subdivisions, and definitions for several of the major syndromes helps to emphasize their arbitrary nature. It also invites formal comparisons, which may help to provide the evidential base for better categorization and definition in the future. It is likely, too, that for financial reasons, the American classification will be revised more frequently in the future than the *International Classification*, and some sections of the nosology may need to be revised quite quickly in the light of etiological research.

The Fifth Edition of the American Psychiatric Association's Classification (*DSM-V*)

DSM-V was published in May 2013. The most significant and perhaps controversial changes deal with neurodevelopmental disorders, depressive disorders, substance-related and addictive disorders, and personality disorders. Autism spectrum disorder is the new name for four previously separate conditions, namely, autistic disorder, Asperger's disorder, childhood disintegrative disorder, and pervasive developmental disorder. In addition, communication disorders now include social (pragmatic) communication disorder, the name for a new condition of persistent difficulties in the social uses of verbal and nonverbal communication. The previous bereavement exclusion criterion in Major Depressive disorder in *DSM-IV* has been removed. A new disorder, gambling disorder, has been added to the substance-related and addictive disorders. Finally, personality disorders now have a reduced (moderate) level of impairment in functioning as criterion with the implication of an increase in the numbers liable to receiving a diagnosis of personality disorder. These changes generated considerable debate in the lead up to publication of *DSM-V*. Allen Frances (2009), who had been the head of *DSM-IV* Task Force, argued that there was no need for a 'paradigm shift' in the structure and approach of *DSM-V* in comparison to previous editions. Particularly of concern was the idea that the threshold for diagnosing a condition might be lowered and that this was liable to result in "wholesale imperial medicalization of normality that will trivialize mental disorder and lead to a deluge of unneeded medication treatments – a bonanza for a pharmaceutical industry."

Shortcomings of Contemporary Nosologies

Uncertain Validity

The most obvious weakness of both contemporary nosologies is the limited evidence for the validity of most of their constituent categories. The combination of a limited understanding of the etiology of most mental disorders and the lack of evidence for the natural boundaries or 'zones of rarity' separating their clinical syndromes (*see* Differential Diagnosis in Psychiatry) means that most existing diagnostic concepts and definitions are not securely based. There are exceptions, of course. The etiologies of, for example, Huntington's chorea, Down's syndrome, the Fragile X syndrome, and Creutzfeldt Jacob disease are all well established, and enough is known of the neuropathology and etiology of Alzheimer's disease and vascular dementia, and of the various syndromes associated with the use of psychoactive substances, for them to be reasonably secure. But the same cannot be said for most of the other major syndromes. For many, there is cogent evidence that genetic factors are making a major contribution to their etiology, and that life experiences and other environmental factors are also involved. It seems increasingly likely, though, that many different genes, each on its own of relatively small effect, are responsible for the genetic basis of most syndromes, and that some of these genes are risk factors for more than one syndrome – for affective as well as schizophrenic psychoses, for example, or for anxiety states as well as depressions. Some adverse life experiences appear to predispose to a similarly broad range of apparently unrelated disorders. In essence, these two nosologies may have sacrificed validity for reliability. This point is underscored by the statement by the United States of America National Institute of Mental Health (NIMH) (Insel, 2013), on the eve of publication of *DSM-V* to the effect that "the strength of each of the edition of *DSM* has been 'reliability' – each edition has ensured that clinicians use the same terms in the same ways. The weakness is lack of validity. Unlike our definitions of ischemic heart disease, lymphoma, or AIDS, the *DSM* diagnoses are based on a consensus about clusters of clinical symptoms, not any objective laboratory measure." NIMH concluded that there was a need for a new approach, based on biology as well as symptoms and proposed a new Research Domain Criteria (RDoC), which is a hybrid of a dimensional approach mapped to cognitive, circuit, and genetic aspects of mental disorders. It is far too early for the full implications of this proposal to become clear.

The Dimensional and Hybrid Alternative

The statement by NIMH once again points to the fact that current genetic, or indeed, other findings do not support a categorical framework of classifying mental disorders. For this reason, at least, the possibility of representing variation in symptomatology by dimensions rather than categories needs to be considered. The idea is not, of course, new. Wittenborn developed an elaborate multidimensional representation of the phenomena of psychotic illness in the mid-twentieth century, and other psychologists and psychiatrists have subsequently advocated and used dimensional models to portray depressive or chronic schizophrenic illnesses, or even mental disorder as a whole. Dimensional classification solves at a stroke all the problems associated with boundaries and comorbidity, and may also be a powerful means of predicting outcome. Even so, there is no realistic prospect at present of any formal national or international classification adopting a dimensional format. Medicine as a whole is too firmly committed to categories of illness, and in any case, dimensions are better suited to the portrayal of variation in populations than to day-to-day decisions about the treatment of individual patients. This does not mean, though, that dimensional systems may not have an important role for research purposes, or as an experimental alternative to a traditional nosology.

Future Developments

In time, as understanding of the underlying determinants of most of the major syndromes slowly accumulates, mental disorders will cease being defined by their syndromes and be defined instead by their neuropathology, or perhaps by a characteristic combination of genetic risk factors, neuroimaging, circuitry abnormalities, and so on. This may not happen quickly, and when it does, the classification of mental disorders – if they are still so-called – may bear little resemblance to our present nosologies. What has to date been missing in the development of nosology and classification systems in psychiatry is the importance of social and cultural factors in shaping and determining the structure of the classification systems, the actual content and the formal criteria for determining class membership of the basic categories, and perhaps most importantly in clarifying the definition of boundaries between disorders. Social and cultural determinants undoubtedly influence the development, presentation, and behavioral response to emotional and psychological distress. Some would argue that language too has substantial influence not only in how distress is communicated but also in how it is experienced. Thus, future developments will have to take account of the ways in which social and cultural factors modify or mediate the experience and expression of psychiatric disorders. It is true that there are global, pan-cultural factors (etic) at play and implicitly constructing the ways in which human distress is manifested but it is equally true that local and parochial social and cultural factors (emic) also have significant influence. The so-called culture-bound syndromes may then have a place in the international classification systems that do not consign these conditions to the status of curios but to legitimate expressions of distress that are either unique or capable of being collapsed into existing nosology. In the immediate future, however, major change seems improbable.

Abstract

This article reviews anthropological and sociological perspectives on nostalgia. It discusses collective nostalgia during times of rapid change as a response to insecurity and uncertainty. It addresses nostalgia for a past way of life due to a widespread sense that strong emotional bonds to other human beings and to community have diminished. It explores the romanticization of rural areas, small towns, and villages, of cultural calendars, and of childhood accompanying collective nostalgia in many parts of the world, as a reaction against urban and industrial anomie. It notes nostalgia's frequent collapse of time and place, with rural areas of the present nostalgically equated with the past, or desires to return to a geographical place of childhood really reflecting a desire for a past time. It situates collective nostalgia in theoretical discussions of community as a multivocal symbol in human life. It discusses 'nationalistic nostalgia,' showing how emotionally laden nostalgic sentiments are used in the nationalistic invention of states as imagined communities. It discusses ways where nostalgia for a lost past, rather than stagnating people in the past, can be a collective means to move forward into the future. It explores how anthropology itself has been viewed as the nostalgic conscious of the modern world for remote, small-scale, or preindustrial cultures and lifeways seemingly lost or sacrificed to modernity. It addresses earlier attempts at salvage anthropology, discussing these in relationship to both a positively espoused 'critical nostalgia,' and a negatively viewed 'imperialist nostalgia.' Finally, it addresses more recent trends in the anthropology of nostalgia that consider how nostalgic projections are used differentially by different elements within a culture in the on-going negotiation of culture, and how processes of world systems, and accelerating trends of globalization and transnationalism influence or induce cycles of collective nostalgia.

Nostalgia Isn't What It Used To Be, proclaims the title to actress Simone Signoret's autobiography (1978). Nostalgia, particularly for a romanticized version of the past as remembered, or imagined, accompanies feelings that life does not seem quite as vivid, or quite as good, as it did in an earlier, more golden time. Signoret's ironic title actually epitomizes this nostalgic sense by suggesting that even the present's poignant pangs of sentimental longing for the past do not seem either quite so romantic nor quite so melancholic as they once did, hence culminating in a nostalgia for a presumed more authentic nostalgia. The title also echoes a contemporary moment in anthropology, in which the anthropological exploration and study of nostalgia is not what it used to be. To explore these issues, this article will discuss nostalgia in individual and collective life, and also discuss transitions and trends in anthropological approaches to nostalgia, linked to the recognition of ongoing historical and global processes affecting human life and cultures.

At the individual level, nostalgia involves sentimentalized longings for the past. Most often, however, this is a combination of a remembered, an imagined, and a recreated past, which in the nostalgic mind-set seems much better – more benevolent, loving, and problem-free – than the past actually was. Individual nostalgia often involves recreated memories of childhood as a time of innocence, when life seemed to follow a meaningful, and patterned course, and one felt embedded in a nexus of human and humane relationships, rather than encumbered by bureaucratic and legalistic ones. Childhood is thus often focal to nostalgic memory and recalled as unproblematic, despite having been fraught with its own problems and tensions. At the collective level, the anthropology of nostalgia attempts to understand how and why such flushes of romanticized longing for the past that individuals periodically feel, become part of the collective imagination. The anthropology of nostalgia seeks to explain why nations, communities, or other collectivities of people seem to experience widespread cycles of nostalgic reminiscing for a presumed shared past.

Uncertainty, Change, and the Collective Imagination

The anthropology of nostalgia suggests that collective nostalgia waxes in times of transition or uncertainty. Increasing nostalgic sentiments frequently underlie a collective identity crisis indicating a sense of confusion or uncertainty surrounding a proclaimed cultural or national identity, or a sense that it is threatened. Increasing urbanization, technological changes, and globalization, all of which can cause swift changes in local lifestyles and cultures, can also give rise to collective nostalgia. Even among peoples or cultural groups seeking change, a seemingly contradictory combination of the rhetoric of progress, with an increase in rhetoric of nostalgia is frequently noted. The anthropology of nostalgia suggests this apparent contradiction is really a corollary response, indicating a fundamental ambivalence to sudden change and so-called modernization. Some anthropologists, such as Ivy (1988, 1995) contend that the contemporary condition of postmodernism, typified by rapidly changing lifestyles accompanied by the pronounced sense that life is shifting and uncertain, induces collective nostalgia.

The sense that life is changing and uncertain can also be associated with the feeling that one no longer has strong emotional bonds to other humans. In his treatise on the sociology of nostalgia, Davis (1979: p. 141) contends that collective nostalgia is often a response to cultural transitions that leave masses of people with feelings of loneliness and estrangement. According to Davis, such nostalgia is part of

a "collective search for identity," which "looks backward rather than forward, for the familiar rather than the novel, for certainty rather than discovery" (Davis, 1979: pp. 107–108). The past, since it has already occurred, emerges as a perceived anchor of stability. Smith (1982: p. 128) notes that the "past will always seem more stable than the present." Therefore, images of the past are invoked to offset the perceived threat of cultural change or identity loss. However, these tend to be highly romanticized images of the past. Tuan points out that "the cult of the past calls for illusion rather than authenticity" (1977: p. 194).

Nostalgic projections of a sentimentalized past involve what Hobsbawm and Ranger (1983) call 'invented traditions.' This term does not necessarily mean such traditions are false, but rather recognizes that the past is constantly undergoing recreation and reinvention by those in the present, in response to present needs.

Country, Community, Childlike, Calendric: The Time and Place of Nostalgia

Anthropologists working in different areas of the world have noted that collective nostalgia frequently romanticizes rural areas, a sense of community, childhood, and calendric rituals once more frequently or more intensely engaged in. Romanticization of the countryside, smaller communities, or rural life is common in collective nostalgia. Increasing urbanization often draws people away from small towns and villages where they belonged to networks of relationships, into the anonymity of city life. This influx of population into cities can also break down existing urban communities. Concomitantly, increasing industrialization, technological development, and globalizing economic systems change not only the methods humans use in productive work activities, but the relationships constructed via these activities. The *gemeinschaft* involvement thought to characterize preindustrial communities, in which life and work found meaning within a network of social relationships, is replaced by *gesellschaft* society, in which human interactions are more purely economic or business exchanges (Toennies, 1957). Romanticization of rural areas can result from urban anomie, or from frustrations with a perceived *gesellschaft* lifestyle, even for those still based in rural or smaller communities.

Romanticization of rural life frequently is noted in areas that have undergone rapid urbanization and industrialization. In Western Europe, industrialization created a romanticized image of the preindustrial countryside. Twentieth-century North America saw periodic flushes of nostalgia for small town life. Some Asian areas, such as Japan (Creighton, 1997, 1998) and Taiwan (Harrell, 1994) experienced nostalgia for agrarian village life after rapid industrial or economic growth.

Such romanticization of rural life suggests a desire to negate feelings of estrangement, by imagining a place and time of belonging. The particular images of rural life vary in each area noted, but all suggest a desire to return to a closer bond with nature, and to the nexus of reciprocal human relationships idealistically projected as typifying 'home town' or 'home village' life. Affirmations of a rural centrality, of the countryside, or of a 'back-to-nature' lifestyle, proffer the hope that a return to the presumed virtues of the past can offset the negative consequences of industrialization and technological development. The nostalgic emulation of deeply embedded human relationships thought to characterize rural areas, and more 'natural' lifestyles, involves a quest for community and the desire to affirm a collective identity.

'Community' is a powerful, multivocal symbol in many cultures. Despite variations in its particular ideal constructions, it generally suggests a desire for belongingness, to an essential need for human interaction in order to lead meaningful lives. Modern nostalgia, as a response to widespread feelings of homelessness and feared cultural loss, often projects symbolic images of a past rural existence to address the threat of estrangement by embracing an ideal of collective belongingness that represents 'community,' the 'good life,' 'wholesomeness,' and moral virtue.

Nostalgic projections of a home town, or home village past, for individuals who actually experienced these often represent what Bellah calls 'communities of memory.' According to Bellah (1985: p. 154), people who grew up in 'communities of memory' know the stories of a community's past, share its ideal values, and understand what it means to participate in the ritual, aesthetic, and seasonal practices that defined the community as a way of life. However, such imagery can invoke intense nostalgia even among those who did not grow up in such communities through the construction of the parallel 'communities of imagination.'

Nostalgia for a past way of life, which rural imagery suggests, is associated with nostalgia for the personal past, suggesting childhood. Sentimentalized projections of community and of childhood reflect the desire to find a 'place' where one belongs and feels secure. In mass nostalgic longings, there is a tendency to collapse time and place dimensions. Rural areas are geographical places that exist contemporaneously with urban areas. However, in the collective landscape of nostalgia, rural areas become symbols of an earlier existence. Childhood is a time in people's lives. However, in the nostalgic imagination, this time becomes a place. Childhood becomes that place where one felt sheltered and secure. Reflecting this emphasis on childhood, nostalgic imagery frequently projects maternal tropes. Both 'mother' and 'community' suggest intimate places of nurturance. For the young child, mother is not just a person who provides love and warmth, but also according to Tuan (1977: pp. 137–138) the child's primary 'place,' a 'haven of stability' where "fundamental needs are heeded and cared for without a fuss." The idealized past community is likewise that 'place' where one belonged, where one had obligations to others, and where one could depend upon others.

Calendric rituals and holidays are a focus of collective nostalgia. Cultural calendars punctuate experience with special days laden with symbolic meanings that have the capacity, in Zerubavel's (1981: p. 46) terms, to "synchronize the sentiments of a large number of people" by creating "emotional rhythms that affect large collectivities." Special calendric events integrate community life. They also play important symbolic and affective roles in both the nostalgic remembrance of community and the nostalgic imagination of community. For example, in an analysis of English Victorian life, Gillis (1989) contends that Christmas offered a nostalgic spiritual pilgrimage, a symbolic

journey of return and reunion to home, community, and 'mother.' In Japan, *Gyoji* are the annual cycle of calendric festival events, emotionally situated in seasonal associations that formerly orchestrated life in agrarian villages. Creighton (1998) describes how the nostalgia-driven 'retro-boom' prompted collective revivals of this traditional calendar of *gyoji* events, in both rural and urban areas, and in new ways in very modern settings such as department stores.

Nostalgia, Claimed Authenticity, Cultural Myths, and Negotiations of Culture

Whereas early anthropological inquiry tended to look for a shared similarity of understandings or world view among members of a culture, in more recent decades anthropology has increasingly explored culture as the organization of diverse elements, and with greater attunement to dynamics of power structures within societies. This orientation recognizes culture as something negotiated rather than fixed and something continually in the process of renegotiation, exemplified by Clifford's (1986: p. 19) declaration that; "Culture is contested, temporal, and emergent." Attunement to what is nostalgically espoused as vanishing from a culture is important to these considerations of culture as emergent and negotiated. Often, what is lamented as the past culture, and corresponding past values and virtues of the culture, or bemoaned as diminishing might actually be what certain members of the culture, whose interests such projections serve more, wish to assert as more 'culturally authentic' as a means of implementing or reimplementing such cultural orientations. What is nostalgically claimed to be 'our authentic culture,' which is eroding, may actually be a means of perpetuating a self-asserted myth about the culture or aspects of it, rather than represent the reality of past experience.

Examples of gender assertions help reveal this. Often reflections on 'traditional gender roles' mask desires to shape gender roles in a particular manner or constrain people within certain roles, based on nostalgic projections that things were different – and better – in the past. The commentary of the proverbial 'grumpy old man' that "back in my day, we did n't need this Women's lib stuff" denies the actual situation in which women (along with many men) were enmeshed in restrictive and oppressive gender expectations. Frequently expressed beliefs in traditional roles tend to reify them, and erase the actuality of past conditions. For example, in many industrial (or postindustrial) societies the image of the 'traditional woman' as an unemployed homemaker masks the reality that many women were – and had to be – in paid work in the past as well as in the present and potentially denies the validity of struggles for better employment conditions for women with the false suggestion that this was or is unnecessary. Such imagery can also be projected outward. For example, many in the West hold an image of the 'traditional Japanese woman' as unemployed, whereas statistics show women in Japan were in paid employment in relatively high and consistent percentages from the beginning of such statistics taking in the early 1900s (Brinton, 1993).

Nostalgic beliefs and representations of the past can also obviate against struggles of social groupings based on other criteria (ethnicity, age, abilities, lifestyle) to be as readily recognized as part of the cultural context. Nostalgic projections of a group's past culture, virtues, or values can also be used by nation-states to evoke nationalism or to prompt negative feelings toward other countries and groups of people in the fostering of positive feelings for one's own country or group.

Nostalgia and Nationalism

Anthropologists have pointed out that nostalgia is used to promote nationalism, through the projection of emotionally laden images, which are then linked to an asserted national way of life. This can involve a positive affirmation of a proud collective identity for a nation, or conversely, a negative and dangerous fostering of ultranationalism, or one that promotes negative feelings about those in other countries or as members of other ethnicities. In his famous treatise on nationalism and invented communities, Anderson says all national communities are imagined and stresses the importance of understanding "the style in which they are imagined" (1985, p. 15).

The nostalgic invocation of a presumed pristine past, an essentialized past culture, and sentimental reaffirmations of nostalgic holidays, are part of the stylistic imagination of national communities. Anderson claims that Christmas in modern Western nations functions as a calendric event, which helps perpetuate "that remarkable confidence of community in anonymity, which is the hallmark of modern times." Despite its appeal in different Western nations, its sentimentally loaded symbolic associations with growing up in a particular place, allow it to be associated with an imagined national community. Likewise in many Asian countries, New Year festivities are frequently used to reaffirm national identity, even though the holiday exists and is celebrated in different forms in other places.

Nostalgic associations with childhood experience are also used to promote nationalistic sentiment. 'Motherhood' frequently becomes a dominant, multivocal symbol used in the promotion of nationalism in diverse nation-states. Creighton (1991) explores the irony of motherhood as a nationalistic symbol. 'Mother' as a symbol could suggest a universal or shared humanity, since everyone presumably had a mother. However, mother symbolism is frequently used to emphasize a nationalistic identity and the exclusion of outsiders, by projections of a culturally specific mother prototype that is then linked to national identity.

In times of political, social, or economic strain, global or regional uncertainty, such uses of nostalgia in the promotion of nationalism can usurp grass roots attempts to reinvigorate bonds among people in local communities. Nationalistic uses of nostalgia can obviate against attempts to build associations that foster closer ties among human beings that go beyond national boundaries. Nationalistic nostalgia offers a sense of belonging to an imagined national community, but it is a form of belongingness, which frequently requires the exclusion and even repudiation of nonmembers. As countries vie for positioning on the world stage, rights over territory or resources, nostalgic longings of the imagined past can be actively utilized

by nation-states to prompt negative feelings toward current members of other nations based on reiterations of past wrongs, tensions, or glories lost, rather than solely focusing on solutions to help recognize and remedy previous wrongs.

There are sometimes reverse cases in the imagination of a (new) national identity in which nostalgia reflects a longing for a past not necessarily romanticized nor necessarily any longer desired. The term 'ostalgie' has been associated with postsocialist yearning in the former East Germany after reunification of Germany as one nation, to describe a yearning for what is lost even when one knows or believes the present is better than the past. Thus 'ostalgie' brings out a particular paradox of nostalgic possibilities.

Anthropology as Modernity's Nostalgia: Salvage Anthropology and Critical Nostalgia

It has been suggested that anthropology has served as the nostalgic consciousness of the so-called modern world. Anthropology's earlier focus on remote small-scale societies has been thought by some to reflect a nostalgia within the modern world for the type of societies and human relations possible in less industrialized or capitalistic systems. The movement for 'salvage anthropology,' referring to the drive to record presumably vanishing cultures before they disappeared, suggests this sort of nostalgia for possible past human lifeways. Associated with salvage anthropology was the concept of 'critical nostalgia' within anthropology suggested by Williams (1973) and discussed by Clifford (1986). Critical nostalgia as cultural analysis involved exploring what were frequently conceptualized as cultural forms anchored in the past as alternatives to the structures and organizational imperatives of present cultures otherwise seen as unavoidable and hence 'naturalized' (seen as 'natural' rather than as human constructions) by those living in modern societies. While some anthropologists considered 'critical nostalgia' as something potentially positive allowing for a critique of postmodernist societies, others have seen such tendencies to posit remote or seemingly exotic cultures nostalgically more negatively and have designated such practices as embedded in 'imperialist nostalgia' (Rosaldo, 1989).

Newer Trends in Anthropology and the Study of Nostalgia

As indicated above, since at least the mid-1980s anthropology tends to explore and analyze culture not as essentialized or involving a priori forms, but as enmeshed in on-going processes of reaffirmation, potential transition, and negotiation by inside as well as outside actors and elements. Cultures are no longer perceived as 'vanishing' in the sense that culture is viewed as processual. Culture is seen as emergent, and as something influenced by historical circumstances and larger world systems. In more recent years, the past one to two decades, there has been increasing emphasis within anthropology toward understanding how accelerating forces of globalization and transnational flows have affected cultures in both macro- and microcontexts and a greater emphasis on this in academic inquiry (Appadurai, 1996, 2001; Hannerz, 1996; Robertson and White, 2003; Tsing, 2000; Brooks and Normore, 2010). Thus greater attention has been paid to issues of so-called glocalization (Robertson, 1992, 1995) or understanding culture change in local contexts as entwined with globalizing processes. The anthropology of nostalgia has become increasingly important as a result. Anthropology still attempts to understand how and why sentiments of nostalgia spread through communities or collectivities or become at times more frequently or loudly voiced collectivity. As studies of globalization and transnationalism have become more important within anthropology, these trends are also looked at in addressing collective nostalgia, which is seen as potentially increasing or expanding due to the heightened effects of these trends, the spread of changes and the speed of changes resulting from them. The greater attunement to these larger and often seemingly external influences on cultures and individuals within them, does not replace an attempt to understand the construction of cultural idioms and meanings. The anthropological exploration of nostalgia brought on by such conditions is still about understanding the nature of self in relationship to society, but it also increasingly recognizes the need to understand the effects of larger world systems operating upon local cultures, and how cultures are embedded in and affected by historical processes, along with larger world economic systems, and increasing trends of transnationalism, translocalism, globalization, and glocalization.

Conclusions

The anthropology of nostalgia attempts to understand why there appear to be periods of mass nostalgia. Anthropologists have noted that collective nostalgia frequently accompanies or follows periods of change, uncertainty, or alienation. The collective landscape of nostalgia in industrialized or post-industrialized societies is typically rural in nature, reflecting an apparent collapse of time and place in the human imagination. Rural areas exist in present time, but are romantically envisioned as representing a past, more pristine way of life. In this collective nostalgic romanticization, place has been confused with time. Significant people of childhood, such as mother, and calendric holidays of a given culture that are emotively experienced during childhood, have strong nostalgia-inducing capacity. In this collective nostalgic romanticization time – the time of childhood – has become a place, a place where security and belongingness seemed assured.

Nostalgia can be channeled to promote nationalism through the projection of emotionally laden symbolism, which is then asserted to represent 'our way of life,' making the nation-state into an 'imagined community.' Anthropologists call this an 'imagined community' because in real communities the ties that bind people are created through actual, on-going, personal interactions. The use of nostalgia to promote nationalistic sentiment can have positive consequences in creating positive collective identity, or negative consequences in fostering ultranationalism, or hatred toward all members of another nation or grouping of people. Projections of a nostalgic

longing for a supposedly more authentic past, can also represent attempts of certain elements within cultures to inscribe or reinscribe forms of culture they find more desirable or which better suit their own interests relative to other elements of the culture, by making it appear that this was the once shared and understood culture.

Collective nostalgia can involve a melancholic longing for the past that prevents people from moving forward. However, many anthropologists suggest that collective nostalgia can also have positive effects, and help enable people to redirect themselves toward future goals. Nostalgic recreations of the past can inspire people to attempt to create deeper human relationships, and a stronger sense of community in their present lives. Nostalgia for the past can be part of a constructive process that allows people to deal with the uncertainty of the present in order to move forward. Collective romanticized sentiments help create a nostalgically imagined assertive linking of the present with the past, and thus with the future. Images of a presumed past in which life seems to have been more stable and loving can help people to offset the threats of insecurity and alienation in the present, allowing them to move forward into an uncertain future with renewed assurance that there is a continuity between past, present, and future, and that the human values they associate with the past still do and will continue to exist.

Anthropological explorations of remote, small-scale, or seemingly 'exotic' peoples at times spoke to the nostalgia of groups in postindustrialized societies as representing possible alternative modes of existence now lost to them. Some have suggested that anthropological studies at times reflected a nostalgic atonement for worlds destroyed in the processes of modernization (Fischer, 1986: p. 200). At one time attempts at so-called salvage anthropology sought to document and preserve the knowledge of cultures, with the possible suggestion that such preservation could possibly permit regenerative possibilities for future generations. Along with this a movement within anthropology designated as 'critical nostalgia' sought to explore such possibilities with an attempt to better the conditions of humanity by considering alternative lifeways shown by differing cultures, with the possibility of implementing aspects considered desirable into the organization of contemporary social systems. For some this is seen positively as potentially enabling a critique, reevaluation, and remaking of postmodern societies, while others view the tendency to contemplate other cultures in a nostalgic mood as more strongly constituting a form of 'imperialist nostalgia.'

The lament of modernity, represented in the title of Signoret's autobiography that "Nostalgia isn't what it used to be" suggests that even a nostalgia for nostalgia may be part of the modern condition. Whether or not nostalgia is what it used to be, the anthropological study of nostalgia is not what it used to be. In the past decade in particular, anthropology has taken a closer view of how accelerating processes of globalization, glocalization, translocalism, and transnationalism are reflected in collective surges of nostalgia. The anthropology of nostalgia still seeks to understand what nostalgic longings for the past reveal about the human condition, about collectivities and about individual social actors within cultural contexts. However, it adds to this a greater attunement to how self and society in localized cultural contexts is affected by historical processes, macroeconomic circumstances, and global world systems.

Abstract

Frank Notestein did more than any other person in the twentieth century to develop demography as a field of study in the USA, and probably the world. He was a creator of institutions and a synthesizer of ideas. After playing an important role in developing a population program at the Milbank Memorial Fund 1928–36, he became successively the first head of Princeton University's Office of Population Research 1936–59, Consultant Director of the new United Nations Population Division 1946–48, and President of the Population Council, 1959–68. At Princeton he trained a high proportion of the next generation of US demographers. His name is indissolubly linked with the development of demographic transition theory, emphasizing the central role played by deliberate fertility control, the importance of massive social and economic change, and the global nature of both mortality and fertility declines. More controversially, he also argued from about 1945 that governmental intervention in developing countries, assisted by external technical aid, could and should hasten fertility transition and limit population growth. He forged the Population Council into an instrument for both helping to achieve these aims and measuring the achievement.

Life and Career

Frank Notestein did more than any other person in the twentieth century to develop demography as a field of study in the USA, and probably the world. He was born on 16 August, 1902, in Alma, Michigan to a family with academic connections. His undergraduate education was in the mid-West in Alma and Wooster colleges, but he earned his Ph.D. in Economics at Cornell University. There he came under the influence of Walter Willcox, which was important both because Willcox was interested in social and population statistics and because of his connections with the Milbank Memorial Fund (MMF), New York, which was to become an important early funder of population research. At Wooster, Notestein met Daphne Limbach whom he married in 1927.

Notestein worked with Edgar Sydenstricker from 1928 to 1936 helping to establish the MMF's population program, carrying out studies of both differential fertility and contraception, and arranging for MMF to fund a demographic survey in rural China. During this time the *Milbank Memorial Fund Quarterly* became, and remained for over a decade, the primary journal where demographic research was reported. In 1936, Frederick Osborn convinced Albert Milbank to fund Princeton University to establish the Office of Population Research (OPR). This was the first program in the USA to combine demographic research and graduate education. Notestein became its first head, 1936–59, directing and synthesizing its work with profound consequences for demographic thought. Because of Princeton's departmental structure OPR's faculty were assigned to appropriate university departments (Notestein to the Department of Economic and Social Institutions), as were its students for most of their course work. OPR provided a single course, given for the first years solely by Notestein, for which it was later to award its own certificate. This was where most of OPR's demographic discoveries and theories were first taught. OPR, because of its head start and its high standards, provided from its faculty and students an extraordinary proportion of the leading demographic teachers and researchers as the discipline expanded through the USA, and indeed the world, in the second half of the century. The two-year-old bibliographical journal *Population Index* was moved to OPR and Notestein became one of the editors.

Notestein took leave from OPR during 1946–48 to become the first Consultant Director of the new United Nations Population Division, which acted as the secretariat for the United Nations Population Commission. Ryder (1984, p. 10) believes that the decision that the United Nations should have such a commission was probably influenced by OPR's wartime research on demographic change in Europe, commissioned by the League of Nations. Notestein left Princeton in 1959 to become President of the Population Council, finally to retire from the Council back to Princeton in 1968 to the position of Visiting Research Demographer at OPR. The Population Council was established as a result of a meeting in Williamsburg, Virginia in 1952. It was held on the initiative of John D. Rockefeller III, but Notestein prepared the agenda and appears to have arrived with a clear concept of the form such an institution should take. For some years, the Council was the only organization which could provide expert advice to Third World governments on contraceptive technology and the establishment of family planning programs. During Notestein's presidency its annual budget rose from US$1 million to US$11 million and its professional staff from 10 to 90, with an increasing presence in developing countries. It also offered scholarships, predominantly to students from developing countries, to pursue graduate studies elsewhere in demography or reproductive biology.

To understand Notestein's achievements it is necessary to have some knowledge of the man himself. He was plain-speaking and straightforward, as was his prose. He had a great capacity for leadership, often in a fatherly way, perhaps because the Notesteins had no children. He had a gift for creating and building institutions, which was enhanced by his closeness to some of the rich and powerful, notably John D. Rockefeller III and Frederick Osborn. He moved easily between the foundation and the university worlds, partly because he believed that the aim of both should be to improve the human lot. He had great love for Princeton University but

was no believer in the ivory tower. He was strangely modest, saying that others had greater intellectual contributions to make than himself, but that his strength lay in his gift for recognizing ability and providing it with an opportunity. His successors at the various institutions he developed were men he had brought into the demographic field: Ansley Coale at OPR, John Durand in the United Nations Population Division, and Bernard Berelson at the Population Council.

Notestein's world was the institution he was building and a major source of information the seminars and papers of that institution. When first presenting demographic transition theory in its more fully developed form, he described it as 'some of the work which my colleagues and I, of Princeton's Office of Population Research, have undertaken ...' (Notestein, 1943, p. 165). Prominent among the colleagues contributing to demographic theory were Dudley Kirk and Kingsley Davis. The most employed of Notestein's outside sources were two works which significantly appeared in his first year of teaching: *World Population* (Carr-Saunders, 1936), which documented Third World mortality declines and population growth, and *Medical History of Contraception* (Himes, 1936), which showed how ancient were attempts to restrict fertility. In his two most famous papers on demographic transition, 'Population—the long view' (1945) and 'Economic problems of population change' (1953), there are only a couple of references which go beyond these two sources and work that either he or his colleagues had undertaken at MMF, OPR or the UN. All his papers drew quite early on ongoing research projects at MMF or OPR, which themselves were not often fully reported until years later. Many of his papers were given first to conferences of mixed disciplines and achieve their impact from their simplicity, common sense, and clarity. After 1936 surprisingly few of his publications were papers submitted without solicitation to demographic journals. All, as Coale (1979) notes of his writing and teaching, were marked by skepticism, respect for evidence, and insistence on rigor and technical competence.

Contribution to Demography

The greatest support for demographic studies and for their funding came between the World Wars from those in the eugenics movement. Their major concerns were that the lower socioeconomic classes were out-breeding the higher ones (and, they assumed, the genetically brighter) and, in the USA, that immigrants had higher fertility than the native-born. The contribution of Sydenstricker and Notestein (1930) was to present, virtually without comment on the implications for society, technically sophisticated analyses of a sample of previously untabulated 1910 US census returns to show that immigrants had higher fertility than the native-born in the first generation but lower in the second. They also showed there were marked rural–urban fertility differentials and somewhat smaller occupational ones. They tried to free the debate from ideology. After 1936 Notestein ceased publishing in the area of fertility differentials, although it was an important element in the 1941 Indianapolis Survey, which was recommended by a committee of which he was a member. That study was the world's first household fertility and family planning survey and was the direct ancestor of the global programs of such surveys in the later decades of the century.

During the 1930s Notestein, together with Regine Stix, analyzed information from interviews in 1932–34 of women who had attended a Margaret Sanger family planning clinic in 1931–32. Three conclusions were to be taught to all who passed through OPR. The first was that deliberate fertility control completely explained the fertility transition and that it did not have biological origins. The second was that 'New patterns of living and new values brought growing interest in family limitation that spread the use of known methods and stimulated the development of new ones. In a real sense, modern birth control is as much the result of new interest in family limitation as its cause' Stix and Notestein (1940, p. 150). The third conclusion, deriving from the discovery that most of these women (predominantly Jewish refugees from Europe) had earlier employed *coitus interruptus* (withdrawal) to limit fertility, was that all societies at all times could have reduced family size if the socioeconomic and cultural circumstances had made this desirable.

Notestein's name is most strongly linked with demographic transition theory, which is as important an intellectual framework in modern demography as evolution is in biology. In its simplest sense, namely, as societies evolve and become richer, mortality falls, to be followed later by a decline in fertility, the concept existed all through the twentieth century. Notestein taught demographic change within such a framework from the inception of his OPR course. His Cornell supervisor, Willcox, had published a paper drawing these conclusions in 1916, and Warren Thompson had divided the process into analytical stages in 1929. Notestein's and OPR's contributions were to identify the conditions of fertility decline, the role of contraception, the great spurt of population growth which occurred before the transition was over, and the spread of the phenomenon. This was greatly facilitated by the sponsorship of four major studies of demographic change in Europe at OPR by a division of the League of Nations transferred from Geneva to Princeton for the duration of World War II, and subsequent funding by the Carnegie Foundation through MMF. This work was published in the period 1944–46, but by February 1943 Notestein was reporting to a meeting of the American Philosophical Society the nature of the 'vital revolution,' the growth of population because of the 'lagging transition in growth rates,' the spread of this revolution to Southern and Eastern Europe, and the fact that mortality was already declining in agrarian Asia portending rapid population growth there.

The globalization of demographic theory was permitted by the funding in 1943 by the Geographer of the US Department of State of studies of population change in India (now India, Pakistan, and Bangladesh) and Japan. Later studies were to cover Formosa (now Taiwan), Malaya (now Malaysia), and Lebanon. Notestein's interest in Asia had been whetted by his part in funding and analyzing the population segment of John Lossing Buck's land utilization survey carried out in China in 1929–31. His conviction that the colonial world would face mounting population growth in the postwar period had been strengthened by the Annual Conference of the MMF in Princeton in early 1944 where OPR researchers gave papers on rapid population growth in India, Japan, and Egypt, and agreed

that global demographic transition was underway. This led to his paper, 'Population—the long view' (1945), presented to a 1944 conference of food specialists at the University of Chicago, and a 1952 address to a conference of agricultural economists, 'Economic problems of population change' (1953). With these two papers the theory was complete. Notestein maintained that fertility declined first in the urban populations of industrialized societies because of the development there of conditions that eroded the traditional family and ascribed status, favoring instead individualism and self-advancement. The decline was retarded because of the slow erosion of ancient institutions and beliefs which had been required to encourage the high fertility necessary to offset the high mortality of premodern times.

But Notestein was already entering a new stage in his life. He and other OPR researchers had recorded that European fertility had begun to fall centuries after mortality did so, with the result that population of European extraction increased sevenfold. This seemed to be an impossible scenario for agrarian Asia and suggested that mortality decline there might meet a Malthusian barrier strangling both the mortality transition and hopes for rising living standards. Already in 'Population—the long view' (1945, p. 52), he had raised the possibility that Asian population growth might be held to doubling by 'wise and vigorous leadership 'and' studied efforts ... to induce declining fertility.' By 1952, in 'Economic problems of population change' (1953, p. 28), his position was that 'It is within the bounds of possibility that the wise use of modern methods of communication and training to promote higher age at marriage and the practice of birth control would bring a considerable reduction of the birth rate even in peasant societies.' Birth control interventions were increasingly attempted, many with the assistance of the Population Council during Notestein's presidency. Fertility in most of the developing world has since declined, earlier than the OPR researchers of the 1940s thought likely, but neither Notestein nor others at OPR incorporated the new vital revolution into a revised demographic transition theory. Perhaps Notestein's stature and influence rested most on the extraordinary extent to which most of his colleagues and students retained the consensus which had been reached in OPR during the 1940s and which he expressed so well.

Revisionists

The movement of Notestein and others toward being more involved in policy formulation and less the detached intellectual observer disquieted parts of the academic demography community. Dennis Hodgson (1983, pp. 2–3) saw this change as being unfortunate, from the scientific point of view, arguing that 'There is a tendency ... for crisis research to be policy research rather than to be strictly academic in nature.' He contrasted this with an earlier, perhaps happier period, when 'Understanding, not change, was the goal.' Simon Szreter (1993) went much further and attributed the changes in Notestein's and his colleagues' interpretations and attitudes to demographic change to their appreciation of the USA's strategic interests during the Cold War period.

Hodgson's criticism probably would not have worried Notestein. He had always held that the overriding purpose of research was to help the human race, writing in his last published article that he was 'both a foundation and university man,' which he did not find incompatible, because most social scientists are 'reformers who are basically interested in the interplay of evolving technology, socioeconomic institutions, and population change as major determinants of the human condition' (Notestein, 1982, pp. 651–687). He had never ruled out policy interventions but regarded them as not only desirable but even to be expected, not only on the mortality side of demographic transition but also on its fertility side. He regarded them as social experiments worth undertaking and studying. His concluding chapter to Stix and Notestein (1940, pp. 150ff.) referred to the need to do something about the high fertility, poverty, and human suffering of half the world, and then discussed possible family planning interventions in distressed areas of the USA. His acceptance of assistance from the League of Nations, the Department of State, the World Bank, and others shows his determination to fund OPR adequately to investigate to its fullest the demographic transition as it had occurred in Western European populations and as it moved around the world. Indeed, if he had not done so, we would have heard little of him or of OPR. Even his later papers place less emphasis on saving the world than on giving priority to demographic research and its funding. The charge that Notestein gave priority to Asia because it was the prime area of American strategic interest, especially as China became communist (Szreter, 1993, pp. 675–680), overlooks the fact that Notestein regarded Asia as the main continent facing potential Malthusian pressures throughout his academic life.

Frank Notestein died at 80 years of age, of complications arising from emphysema, on 18 February 1983 in retirement at Newton, Pennsylvania, only a short drive from Princeton.

Abstract

Number is a much more challenging category than is generally believed. While in languages like English it is only a nominal category, for quantifying the number of entities, in many languages it is rather a verbal category, which indicates the number of events. Number is an obligatory category in English, and yet in many languages the use of the plural is not obligatory and it is used only when it is important to mark number. In English the majority of nominals can mark number, from the personal pronouns and nouns denoting persons, down to those denoting inanimate objects, even including some nouns denoting abstracts. Many languages restrict the number opposition to fewer nominals, namely those which are high in animacy. Animacy also helps determine the varying semantics of the category of number. While languages like English are restricted to singular and plural, many languages have a wider range of possibilities. We wish to establish how many number values natural languages may have, and which they are. Besides the well-known values, namely singular, plural and dual, there are also trials and paucals, and the largest systems have five members in all.

Number is often taken to be a relatively straightforward category. It is often used as the textbook illustration of an inflectional category, and the situation in languages like English is believed by many to be the normal if not the only one. English makes a semantic distinction, and a formal distinction between, for instance, *cat* and *cats*, *child* and *children*. In fact the number category reveals many surprises, and the system found in English is a rather extreme one, when seen within the space of possibilities established from a survey of the languages of the world. We shall consider characteristics of the English system in turn, showing some of the ways in which it is typical or atypical. We shall give greatest prominence to the question of number values.

Nominal and Verbal Number

In English number is a nominal category, it involves the distinction between instances such as *cat* and *cats*. When it appears on verbs, this is by agreement with a subject noun phrase, as in *the children were playing happily*. The plural verb still indicates the number of children, and not the number of playing events. There are many languages which have verbal number, that is, where the number of the verb indicates the number of events (see Durie, 1986 for examples).

Number as an Obligatory Category

Number is an obligatory category in English. If someone says, *there's a visitor waiting to see you*, when there are several, this is misleading and inappropriate. In many languages, however, the use of the plural is not obligatory, but is used when it is important to mark number. One example is the Cushitic language Bayso:

(1) Bayso (Dick Hayward, personal communications, Corbett and Hayward, 1987)

lúban	*foofe*
lion.GENERAL	watched.1SG

'I watched lion' (it could be one, or more than that)

Another language, from many examples, is the Arawak family language Bare of Venezuela and Brazil (Aikhenvald, 1995, pp. 18–19).

The Nominals Involved in the Number System

In English the majority of nominals can mark number, from the personal pronouns and nouns denoting persons (like *woman)* down to those denoting inanimate objects like *door*, and even to some denoting abstracts like *hour*. Many languages restrict the number opposition to fewer nominals, namely those which are high in animacy (Smith-Stark, 1974). Thus in Slave (an Athapaskan language spoken in parts of the Northwest Territories, British Columbia, and Alberta, Canada) number may be marked on the noun phrase provided the noun denotes a human or a dog (Rice, 1989, p. 247).

The Semantics of Number

As long as we stay with innocent examples like English *cat* and *cats*, the semantics of number look clear, since *cats* is appropriate for more than one instance of *cat*. In fact there are many concealed difficulties: a concise overview of work on number within formal semantics can be found in Link (1998), who shows how the study of plurals relates to different movements in linguistic semantics, and provides a substantial bibliography.

If we move from ordinary plurals to consider *I* versus *we*, it becomes clear that here we have an 'associative' use of the plural; *we* is most often used for 'I and other(s) associated with me.' At the other end of the Animacy Hierarchy, nouns like *coffee* have a plural, provided they are recategorized: if *coffee* denotes a type, or a typical quantity of coffee, then there is an available plural, as in: *she always keeps three different coffees*, and *we've ordered two teas and three coffees*.

Number Values

A striking way in which English is limited in its number system is in terms of the number values. In English we can distinguish

only between singular and plural. Many languages have more distinctions, and it is these on which we shall concentrate.

The Dual

A common system is one in which singular and plural are supplemented by a dual, to refer to two distinct real world entities. Examples are widespread. We will take Central Alaskan Yup'ik, as spoken in the southwestern Alaska (Corbett and Mithun, 1996); the number forms are: singular *qayaq* 'kayak,' dual *qayak* 'two kayaks,' and plural *qayat* 'three or more kayaks.' The addition of the dual has an effect on the plural, which is now used for three or more real world entities, and more generally a change in system gives the plural a different meaning.

The Trial

While the dual refers to two distinct real world entities, the trial is for three, and it occurs in systems with the number values: singular, dual, trial, and plural. This system is found in Larike, a Central Moluccan language spoken on the western tip of Ambon Island, Central Maluku, Indonesia. (Central Moluccan forms part of the Central Malayo-Polynesian subgroup of Austronesian.) This example is from Laidig and Laidig (1990, p. 7):

(2) *Kalu iridu-ta-peu* *au-na-wela*
if 2.TRIAL-NEG-go 1.SG-IRR-go.home
'If you three don't want to go, I'm going home.'

In this language the dual and trial forms can be traced back to the numerals 'two' and 'three,' and the plural comes historically from 'four.' Such developments are fairly common in Austronesian languages. Sometimes the term 'trial' is used according to the form of the inflections (derived historically from the numeral three), even when the forms are used currently for small groups including those greater than three (and so are paucals) and sometimes the term is used according to meaning (for genuine trials). The Larike trial is a genuine trial, used for exactly three (Laidig and Laidig, 1990, p. 92).

The Paucal

Paucals are used to refer to a small number of distinct real world entities, somewhat akin to the English quantifier 'a few' in meaning. There is no specific upper bound on the use of paucals (their lower bound will vary according to the system in which they are found). Let us return to the Cushitic language Bayso. Besides the general number forms (as in (1), where number is not specified), there are also singular, paucal, and plural. Here is the paucal:

(3) Bayso (Dick Hayward, personal communications, Corbett and Hayward, 1987)
luban-jaa *foofe*
lion-PAUCAL watched.1.SG
'I watched a few lions'

The paucal is used in Bayso for reference to a small number of individuals, from two to about six. (Bayso has this system in nouns but not in pronouns.) The Bayso system is rare; normally the paucal is found together with a dual, so that the number values are singular, dual, paucal, and plural. This widespread system is found, for example, in Yimas, a Lower Sepik language spoken in the Sepik Basin of Papua New Guinea (Foley, 1991, p. 216).

The Largest Systems

It is worth asking what is the largest system of number values. There are claims in the literature for languages with a quadral, for four distinct real world entities, thus giving a system of five number values. It is established that five number values can indeed be found, but the evidence specifically for a quadral is less clear. All the claims come from within the Austro-nesian family and the best documented case is Sursurunga (Hutchisson, 1986, and personal communications), spoken in southern New Ireland. The forms labeled quadral are restricted to the personal pronouns, but are found with all of them, the first person (inclusive and exclusive), the second, and third (**Table 1**).

Here is an example of a quadral form in use (we will retain the traditional label 'quadral,' until we have justified replacing the term for Sursurunga):

(4) Sursurunga (Hutchisson, 1986 and personal communications)
gim-hat *káwán*
1.EXCL-QUADRAL maternal.uncle:nephew/niece
'we four who are in an uncle-nephew/niece relationship'

The 'quadral' has two additional uses. First, in Sursurunga plural pronouns are never used with terms for dyads (kinship pairings like uncle-nephew/niece). Here the 'quadral' is used, for a minimum of four, and not just for exactly four (Hutchisson, 1986, p. 10). Second, in hortatory discourse, the speaker may use the first person inclusive 'quadral' in order to suggest joint action including the speaker, even though more than four persons are involved. These two special uses of the 'quadral' account for the majority of instances of its use. According to its meaning, the term 'quadral' is not appropriate. Rather the forms would be better designated 'paucal.'

Let us now consider the rest of the system of Sursurunga (data and judgments from Don Hutchisson, personal communications). The dual is used quite strictly for two people. It is also used for the singular when the referent is in a taboo relationship to the speaker. This is a special use; the dual's main use is as a regular dual. The trial will be used for three. However, it is also used for small groups, typically around three or four, and for nuclear families of any size. It is

Table 1 Emphatic pronouns is Sursurunga

	singular	*dual*	*'triai'*	*'quadrai'*	*plural*
1 exclusive	iau	giur	gimtul	gimhat	gim
1 inclusive	—	gitar	gittul	githat	git
2	iáu	gaur	gamtul	gamhat	gam
3	-i/on/ái	diar	ditul	dihat	di

Note: á is used to indicate schwa (ə)
Source: Hutchisson, D., 1986. Sursurunga pronouns and the special uses of quadral number. In: Wiesemann, U. (Ed.), Pronominal Systems (Continuum 5). Narr, Tübingen, Germany, pp. 217–255 and personal communications

therefore not strictly a trial, rather it could be labeled a paucal (an appropriate gloss would be 'a few'). We noted earlier that this is a frequent development for the trial. The 'quadral,' as we have just seen, is used primarily in different ways with larger groups, of four or more (an appropriate gloss would be 'several'). This too would qualify as a paucal; we therefore have two paucals in Sursurunga, a paucal (traditionally 'trial') and a greater paucal (traditionally 'quadral'). The plural, as we would expect, is for numbers of entities larger than what is covered by the greater paucal, however, there is no strict dividing line (certainly not at the number five). Using semantic labels, we might represent the system in Sursurunga as having: singular, dual, paucal, greater paucal, and plural. Sursurunga has a well-documented five-value number category. There are certainly other languages with five number values; we do not have such detailed information as for Sursurunga and there is no certain case of a quadral: it seems that in all cases the highest value other than plural in such systems can be used as a paucal. Besides the split in the paucal, we may also find a split in the plural, with 'greater plurals' of different types, as for instance in Mokilese (Harrison, 1976). Greater plurals may imply an excessive number or else all possible instances of the referent. They are as yet poorly researched, except in a few languages.

Conclusion

Number is indeed a much more complex category than is generally recognized, and the English system, though a common one, is at one extreme of the typological space. We noted that number may be a verbal category as well as a nominal one (but the possibilities are rather more restricted for verbal number). We also saw that number need not be obligatory, that the range of items which distinguish number varies dramatically from language to language, that the semantics of number are affected by the particular item involved, and that the values of the number category can be just two or, in various combinations, up to five. More complex issues, which we have not been able to address here, include various interactions, notably between the forms of marking of number, the particular nominals which distinguish number in a given language, and the systems of number values. For these issues see Corbett (2000).

Numbers and Number Sense

Ian M Lyons, University of Western Ontario, London, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews several canonical signatures of number processing and the proposed theoretical interpretations of these signatures. It examines the biological origins of number sense in humans and nonhuman species alike, how to conceptualize the notion of numbers without symbolic form, and the role that number sense may play in human development. Symbolic numbers are discussed in terms of their history and the leading ideas about how the human brain assigns meaning to these crucial building blocks of modern human society.

Introduction

It is difficult to think of an aspect of modern society that has not been fundamentally shaped by the application of mathematics. Numbers, it may be argued, provide the basic cognitive scaffolding around which mathematical thinking is eventually constructed. The study of how numbers are represented and manipulated at both cognitive and neural levels thus provides a window into how the brain acquires and hones perhaps one of its most effective tools for shaping the world around us: mathematics. At the broadest level, the study of numerical cognition has divided numbers into two categories: symbolic and nonsymbolic. Symbolic numbers typically refer to exact quantities and are typically studied in written (e.g., Indo-Arabic numerals) or spoken (number words) form. Nonsymbolic magnitudes tend to be more approximate in nature – for instance, one may rapidly estimate which of two groups of dots contains more objects without counting or explicit reference to a symbolic numerical label. Number processing in both forms – symbolic and nonsymbolic – has been extensively studied in human children and adults, as well as many different nonhuman species. Methodological approaches tend to be behavioral (e.g., response times and/or error rates in numerical judgments) or neural (e.g., noninvasive neuroimaging in humans, as well as single-cell recording in nonhuman primates).

In the sections that follow, I review several canonical signatures of number processing and the proposed theoretical interpretations of these signatures. I then examine the biological origins of number sense in humans and nonhuman species alike, how to conceptualize the notion of numbers without symbolic form, and the role that number sense may play in human development. Finally, I discuss symbolic numbers in terms of their history and the leading ideas about how the human brain assigns meaning to these crucial building blocks of modern human society.

Signatures of Number Processing

There are several behavioral and neural signatures of number processing commonly found and discussed throughout the field of numerical cognition. Interpreting these effects has helped shape the ongoing debate about how numbers are represented and processed in the brain.

Numerical Distance Effect

Perhaps the most commonly cited numerical signature is the numerical distance effect. Note that the term 'distance' is something of a misnomer here, as it refers strictly to the absolute numerical difference between numbers, and not the physical distance between them. When an individual is asked to decide which of two numbers is numerically greater (commonly referred to as a numerical comparison task), performance depends systematically on the numerical difference between the two numbers. Performance tends to be worse (longer response times and higher error rates) when the numbers being compared are numerically close (e.g., performance on 5 vs 6 is worse than on 3 vs 8). This effect has been shown in both adults (Moyer and Landauer, 1967; Buckley and Gillman, 1974) and children (Sekuler and Mierkiewicz, 1977; Rubinsten et al., 2002). Moreover, neuroimaging studies have shown that brain responses – particularly in the intraparietal sulcus (IPS) – are modulated specifically by numerical distance during numerical comparison tasks (Pinel et al., 2001; Kaufmann et al., 2005; Ansari et al., 2006; Mussolin et al., 2013).

A related effect uses priming instead of comparison as a means of measuring the influence of numerical distance on brain and behavioral responses. In a priming paradigm, participants see a very brief stimulus (called a prime) immediately prior to completing some simple task. For example, when asked to name a number, numerically close primes lead to more facilitation (faster response times) than do numerically distant primes (Reynvoet et al., 2002). This effect is found in children as young as first grade, and is similar to that seen in adults (Reynvoet et al., 2009). The numerical distance between prime and target numbers also modulates neural responses in parietal cortex (Notebaert et al., 2010). In sum, numerical distance effects are present in both adults and children, influence both behavioral and neural responses, and are detectable whether measured via comparison or priming.

Numerical Ratio Effect

Another numerical signature is the numerical ratio effect, which refers to the ratio between two numbers, $(\frac{n_1}{n_2})$, typically where $n_1 < n_2$. (Notice that the ratio effect differs from the distance effect primarily in that the former takes into account the numerical size of the numbers in question. For example the distances between the pairs (2, 3) and (8, 9) are both 1;

 http://dx.doi.org/10.1016/B978-0-08-097086-8.57031-7

however, they differ in ratio $\left(\frac{2}{3} \neq \frac{8}{9}\right)$.) In number comparison tasks (subjects decide which of the two numbers is numerically greater), performance tends to be worse as ratio approaches 1 (e.g., Lyons and Beilock, 2009). Six-month-old infants' looking times are influenced by numerical ratio. For example, if an infant sees 16 items repeatedly displayed on a screen, the infant will look longer at the screen when it changes to 32 items (ratio = 0.5). However, the child will not increase its looking time when the screen changes from 16 to 24 items (ratio = 0.67) (Xu et al., 2005). The ratio at which children can distinguish between such perceptual magnitudes becomes more precise (i.e., closer to 1) as children get older (Halberda and Feigenson, 2008), asymptoting at around $\frac{10}{11}$ in adults (Halberda and Feigenson, 2008; Pica et al., 2004).

The method most commonly used for assessing neural responses as a function of numerical ratio is called adaptation. An individual whose brain is being imaged will passively view several repetitions of a given number (e.g., 6). This passive repetition is associated with a steady reduction in the neural response to the repeated (standard) number; that is, the relevant brain regions are thus 'adapted' (i.e., habituated) to the repeated stimulus (Grill-Spector et al., 2006). Researchers will then intermittently present different (deviant) numbers (e.g., one of 4, 5, 7, 8, etc.) and measure the resulting neural response. One can then plot the brain responses to the deviant numbers as a function of their numerical ratio relative to the standard number. Neural responses in the parietal lobe (especially the IPS) tend to be systematically greater as the ratio between the standard and the deviant diverges from 1 (Piazza et al., 2004; Holloway et al., 2013).

A close derivative of numerical ratio is sometimes referred to as the numerical Weber fraction, or w, which has become an especially popular measure of numerical comparison performance (e.g., Halberda et al., 2008, 2012). One reason for this is that w is an especially strong predictor of how accurately individuals compare perceptual magnitudes (such as arrays of dots). When fitting sample means, the R^2 fit between estimated w and actual error rates is often upward of 0.9 for children, monkeys, and adults (Pica et al., 2004; Cantlon and Brannon, 2007; Halberda and Feigenson, 2008; Lyons and Beilock, 2011).

A few points of caution with respect to w are worth noting, however. First, w is very closely related to numerical ratio. This is because the formula for estimating w when comparing two numbers n_1 and n_2 ($n_1 < n_2$) relies on the value $k = \frac{n_2 - n_1}{\sqrt{2(n_2^2 + n_1^2)}}$, which is very highly correlated with the simple ratio between n_1 and n_2 $\left(\frac{n_1}{n_2}\right)$ (for full details on the formula for estimating w, see Pica et al., 2004). For example, in a stimulus set containing all possible (nonequal) number pairs from the range 1–10, k and $\frac{n_1}{n_2}$ will be correlated at $r = -0.999$. Thus, an estimate of w should be nearly identical to a ratio effect. Second, w can only be assessed with respect to error rates and not response times. This may be especially problematic when examining symbolic number comparisons (i.e., using Indo-Arabic numerals) in adults, where error rates may be very close to zero, and hence the majority of meaningful performance variability is often found in response times. Finally, Inglis and Gilmore (2014) recently showed that test/retest reliability for both w and ratio effects is poor (though see also Price et al., 2012; for issues regarding reliability of symbolic distance effects, see Maloney et al., 2010). On the other hand, Inglis and Gilmore (2014) showed that reliability for overall average accuracy was quite high; hence, if one is concerned with individual differences (e.g., relating numerical performance with other measures, such as math achievement or IQ), then one may be better off forgoing measures related to numerical distance or ratio altogether.

In sum, like numerical distance, the influence of numerical ratio on both brain and behavioral responses has been identified across a wide range of ages, measures, and experimental paradigms. There has been strong recent interest in using w – a close cousin of numerical ratio. While w yields strong fit with performance in limited cases (e.g., error rates when comparing perceptual magnitudes), the usefulness of w is quickly exhausted – for instance, when considering individual differences or cases in which high accuracy rates are expected.

Interpretations

The most common interpretation given to both numerical distance and ratio effects (including w) is that of representational precision. In this view, distance/ratio effects arise because the representations of numerically close numbers are more likely to overlap than are those of numerically distant numbers (Dehaene and Changeux, 1993; Verguts and Fias, 2004; Nieder and Dehaene, 2009). Greater representational overlap makes it more difficult to distinguish between two numbers; for instance, when deciding which of the two numbers is numerically greater in a comparison task, or detecting numerical change in an adaptation or looking-time paradigm. This account explains the distance effect because the representations of 5 and 6 overlap to a greater degree than do those of 3 and 8. The ratio effect is accounted for by the assumption that the representations of larger numbers overlap to a greater degree than do smaller numbers; hence, while 8 and 9 overlap to a greater extent than do 7 and 9 (distance effect), 8 and 9 also overlap to a greater extent than do 2 and 3 (ratio effect).

Empirical justification for these assumptions has arisen primarily from work with perceptual magnitudes (e.g., estimating – without explicitly counting – the number of dots in an array, or which of the two arrays of dots contains more dots; Indow and Ida, 1977). Nieder and colleagues (for a review, see Nieder, 2005) recorded single-cell activity from individual prefrontal and parietal neurons in macaque monkeys while monkeys briefly held a quantity of dots in active memory. The authors found that some of the neurons thus sampled were tuned to specific quantities of dots. For instance, a given neuron might be most active (measured in terms of action-potential spike density) when the monkey temporarily held in memory three dots. Interestingly, the neuron would also fire when the monkey held in mind two or four dots; however, the net amount of activity was less than for the preferred quantity (three, in this example), and activity was still less for one or five dots. In this way, Nieder and colleagues showed that there are numerically tuned neurons in the brain, and that these representations are systematically imprecise (i.e., analog). Neuronal responses

to different numbers overlap with one another (implying a degree of representational imprecision), and this overlap varies systematically as a function of the numerical distance between them (see **Figure 1** for a simulated example based on human data in Merten and Nieder, 2009). Furthermore, both the neuronal evidence discussed above as well as behavioral evidence in humans (e.g., Nieder and Merten, 2007; Merten and Nieder, 2009) show that numerosity and tuning width are positively correlated. Specifically, as the preferred number increases, the width (i.e., systematic imprecision) of that preference also increases (note that this width is in fact constant on a log–log plot). This means that 8 and 9 will overlap more than 2 and 3, which, as discussed above, is consistent with the numerical ratio effect. Finally, neuroimaging evidence in humans also shows ratio-dependent tuning in parietal cortex – at least for nonsymbolic magnitudes (Piazza et al., 2004).

Figure 1 (a) Shows simulated tuning curves based on monkey neuronal data (for a review, see Nieder, 2005) and human and monkey behavioral data (Merten and Nieder, 2009). The *x*-axis is the number of dots in the stimulus, and the *y*-axis is the simulated firing rate. Each curve shows the simulated firing rate for a neuron that is tuned to the number over which it is centered (dashed lines are provided to help identify the curves for 2, 3, 8, and 9). That is, the relative firing rate for a neuron tuned to 9 fires maximally for 9 dots. Notice that this simulated '9-neuron' also fires for 8 dots, but a bit less so than for 9; indeed the firing rate falls off as the presented number of dots (*x*-axis) increasingly differs from 9. Finally, notice that these curves fall off more steeply for neurons tuned to smaller numbers. It is in this way that the width of tuning curves is positively correlated with the number being represented. (b) Plots the degree to which each pair of curves overlap with one another: $\frac{n_1 \cap n_2}{n_1 \cup n_2}$. Overlap proportions for 2 and 3 and 8 and 9 are marked with a dot, which demonstrates the ratio effect.

To briefly summarize, neural evidence is consistent with the interpretation that numerical ratio and distance effects are indicative of an underlying analog magnitude representation: numerically closer numbers show greater representational overlap (distance effect), and this overlap increases as the size of the numbers in question increase (ratio effect). However, the vast majority of this evidence comes from experiments that examined approximate, nonverbal, nonsymbolic, perceptual magnitudes (e.g., dot arrays; hereafter, simply 'nonsymbolic magnitudes'). When we look at symbolic numbers, such as Indo-Arabic numerals, the evidence is not as clear.

For symbolic numbers such as Indo-Arabic numerals, Verguts et al. (2005) proposed an alternative explanation, beginning with the observation that smaller numbers occur with far greater frequency than do larger numbers (both in speech and in written records; Dehaene and Mehler, 1992). Verguts et al. (2005) created a distributed model of number representation with constant representational precision (equally wide tuning curves) for all numbers, but matched number frequency during model training roughly to that reported by Dehaene and Mehler (1992). When performing a standard number comparison task, the model simulated a ratio effect. In other words, to explain the ratio effect, at least for symbolic numbers, one need not assume representational overlap that increases with the number being represented (see also Verguts and Van Opstal, 2005, for empirical verification of this model).

Sasanguie et al. (2011) have since shown that comparison and priming numerical distance effects are uncorrelated. These results essentially force one to choose between comparison and priming distance effects as the 'true' indicator of representational overlap, with the other indexing some other aspect of processing. To this end, Van Opstal et al. (2008) dissociated the notion of a comparison distance effect entirely from the notion of representational overlap. They did so by showing that comparison distance effects obtain for both number and letter comparisons (when asked 'which letter comes later in the alphabet,' participants were slower to compare, e.g., E vs F than C vs H), but the priming distance effect was found only for numbers. Hence, Van Opstal et al. argued that the priming distance effect is the superior index of number representation, and that the comparison distance effect is primarily due to more domain-general mechanisms, such as response mapping.

Another puzzling aspect of symbolic distance effects occurs when participants are asked to judge relative numerical order. Under such task demands, the effect of numerical distance is in fact reversed on trials where the numbers are in the correct order. For example, participants are faster and more accurate when confirming that 4 – 5 – 6 is in order than when confirming that 3 – 5 – 7 is in order (Turconi et al., 2006; Franklin, 2009; Franklin and Jonides, 2009; Lyons and Beilock, 2013). Crucially, no such reversal of the distance effect is found when participants judge the relative order of nonsymbolic perceptual magnitudes (arrays of dots; Lyons and Beilock, 2013). One interpretation is that

highly familiar associations between symbolic numbers (e.g., from the counting sequence) in essence trump the standard influence of numerical distance. Regardless of one's interpretation, the reversed ordinal distance effect demonstrates that simply changing task demands can qualitatively alter the influence of numerical distance on performance, which further calls into question the assumption that symbolic numerical distance effects are a straightforward index of symbolic number representation.

In sum, a common interpretation of numerical ratio and distance effects is that they index underlying representational overlap. In the case of nonsymbolic magnitudes (such as dot arrays), empirical evidence strongly supports this interpretation. However, with respect to symbolic number representation, several lines of evidence converge to render this assumption questionable at best.

Biological Origins – Number Sense

As noted above, adult and infant humans are capable of determining which of the two arrays of objects (e.g., dots) contains more items, even without counting (Buckley and Gillman, 1974). Adults' ability to do so depends on the ratio between the relative numbers of items in each of the two arrays – with a typical limit of about $\frac{10}{11}$ (Cantlon and Brannon, 2007). This pattern of results is robust across cultures and obtains even in individuals whom possess no words for numbers beyond three or four, or other kinds of formal mathematics (Pica et al., 2004). Individuals both with and without formal math education are capable of adding and subtracting such approximate magnitudes as well (Pica et al., 2004; Barth et al., 2006). The ability to process nonsymbolic magnitudes is commonly referred to as 'number sense' (Dehaene, 1997).

Number Sense across Species

When estimating changes in nonsymbolic magnitude, humans and (rhesus macaque) monkeys show a similar pattern of behavior (Merten and Nieder, 2009). A common experimental paradigm used to train and record neural and behavioral responses in monkeys is often referred to as 'delayed match-to-sample,' and it is similar to dot comparison tasks described previously. The difference is that arrays are presented sequentially. An individual sees a single array of dots, which is followed shortly thereafter by a second array. One's task is to determine if the second array matches the first in terms of the number of dots. The benefit of this approach is that one can more transparently record (and hence model) the performance function ('tuning curve') for a specific number – i.e., the first number presented and held in mind during the delay period. (In a standard number comparison task where both numbers are presented simultaneously, it is unclear whether performance and/or neural activity reflects the representation of one number, both numbers, the comparison process, or some combination of all three.) For a specific quantity of dots (e.g., 30), one can plot the probability of a 'same' judgment as a function of the quantity of dots in the second array. Even for quantities as high as 30, both monkeys and adult humans reliably report 'same' most often when indeed the second array contained 30 dots. This demonstrates that both species are capable of processing nonsymbolic magnitudes. Moreover, as the number of dots in the second array shifts away from 30, the probability of a 'same' response decreases systematically as a function of the numerical ratio of the two arrays. In other words, the closer the ratio between the two arrays is to 1, the more likely an individual is to perceive the two arrays as in fact containing the same number of items (thus demonstrating, in both species, the ratio effect, as discussed previously). Interestingly, the function that best describes the decrease in the probability of a 'same' response corresponds to a positively skewed distribution whose overall width increases as the target quantity (the first array) increases (somewhat akin to the curves plotted in **Figure 1**). That is, one can imagine a quasi-normal distribution centered on the target quantity, with a stretched out tail to the right, and a relatively compact tail to the left. Furthermore, the distribution (in both directions) centered on 30 will be wider than that for 25, and that for 25 will be wider for 20, and so on. Interestingly, the function that describes this tuning is quite similar in both humans and monkeys, which suggests a potential common mechanism across species, at least for detecting change in nonsymbolic magnitudes. (Plotted on a linear scale, the distribution widens at a rate of about 0.421 units per unit increase in the target number. On a log-scale, distribution widths are both symmetrical and constant with target number change (Merten and Nieder, 2009).)

The similarity between human and monkey processing of nonsymbolic magnitudes extends to other nonsymbolic magnitudes tasks, such as simultaneous nonsymbolic comparison (Brannon and Terrace, 2002), nonsymbolic ordering (Cantlon and Brannon, 2006), and nonsymbolic arithmetic (Cantlon and Brannon, 2007). Indeed, this ability is common to many species, including dolphins, macaques, capuchins, baboons, wolves, canids, mice, parrots, crows, robins, bees, fish, and even beetles (Agrillo et al., 2009; Armstrong et al., 2012; Baker et al., 2012; Barnard et al., 2013; Beran et al., 2012; Carazo et al., 2012; Nieder, 2005; Pepperberg, 2013; Piffer et al., 2013; Smirnova et al., 2000; Utrata et al., 2012; Yaman et al., 2012 – for reviews, see Agrillo and Beran, 2013; Pahl et al., 2013). In sum, it is clear that the ability to process nonsymbolic magnitudes is not unique to humans, and it is surmised that our ability to do so is part of an innate capacity with deep evolutionary roots (Hubbard et al., 2008).

Number Sense in Early Development

The ability to distinguish visual (Xu and Spelke, 2000) and auditory (Lipton and Spelke, 2003) nonsymbolic magnitudes is present in children as young as 6 months of age. The topography of neural signatures can distinguish between neural pathways related to object identification and nonsymbolic magnitudes; further, this topography is similar in adults, 4-year-olds, and 3-month-old infants, with sensitivity to magnitude centered on the IPS (Cantlon et al., 2006; Izard et al., 2008). Combined with the observation that something akin to a number sense is present across a range of

species, the results from human developmental studies suggest that the basis of humans' ability to process nonsymbolic magnitudes is present from a very early developmental stage, does not require formal math training, and may even be innate (Feigenson et al., 2004; Cordes and Brannon, 2008; Nieder and Dehaene, 2009).

This insight has led various researchers to hypothesize that children's number sense forms the foundation on which more sophisticated, culturally acquired mathematical skills rest (e.g., Dehaene, 1997). Indeed, over a dozen papers in the last several years have demonstrated a correlation between individual differences in adults', children's, and even infants' ability to process nonsymbolic magnitudes with performance on a wide range of formal math achievement tests (Bonny and Lourenco, 2013; Desoete et al., 2012; Gilmore et al., 2010; Halberda et al., 2008, 2012; Libertus et al., 2011, 2012, 2013; Lonnemanna et al., 2011; Lourenco et al., 2012; Lyons and Beilock, 2011; Mazzocco et al., 2011a,b; Piazza et al., 2010; Starr et al., 2013; for a review, see Feigenson et al., 2013). Training on approximate arithmetic (using dot arrays) has also been shown to preferentially improve symbolic math achievement scores (Park and Brannon, 2013, 2014; Hyde et al., 2014). These results point to the exciting prospect that numerical cognition may be a prime example of how evolutionarily ancient neural systems are co-opted by cultural inputs (number symbols) to serve a cognitive ability (mathematics) that is crucial to much of modern human life (Dehaene and Cohen, 2007).

On the other hand, it remains unclear precisely how this process occurs. With respect to training, other studies have shown that training on dot comparison tasks does not improve symbolic math scores (Wilson et al., 2006; Dewind and Brannon, 2012; Park and Brannon, 2014); thus, it is not so much improved processing of nonsymbolic magnitudes per se, but improved manipulation of those magnitudes in a mathematical context (arithmetic) that improves symbolic math performance (Park and Brannon, 2014). With respect to individual differences, the relation between nonsymbolic magnitude processing and math achievement has not replicated consistently (De Smedt et al., 2013), and a recent meta-analysis has shown that the relation between nonsymbolic magnitude processing and math achievement is relatively small ($r = 0.20$ for cross-sectional, and $r = 0.17$ for longitudinal studies; Chen and Li, 2014). Moreover, multiple studies have now shown that this correlation is often entirely eliminated once one controls for basic symbolic number processing abilities (such as number comparison, counting, or number ordering; Bartelet et al., 2014; Castronovo and Göbel, 2012; Fuhs and McNeil, 2013; Göbel et al., 2014; Holloway and Ansari, 2009; Kolkman et al., 2013; Lyons and Beilock, 2011, 2014; Sasanguie et al., 2013; Toll and Van Luit, 2014). In other words, the processing of number symbols appears to be more directly tied to more complex math processing (even after controlling for the fact that both are typically in the same visual format; e.g., Lyons and Beilock, 2011; Lyons et al., 2014).

The critical outstanding question, then, may be to understand precisely how nonsymbolic magnitudes aid young children as they first begin learning to comprehend and manipulate numerical symbols in mathematically meaningful ways. However, even in kindergarteners and preschoolers, the current literature remains mixed. For instance, contrast results confirming a relation between nonsymbolic and symbolic number processing in kindergarten or younger (Bonny and Lourenco, 2013; Jordan et al., 2009; Gilmore et al., 2010; Libertus et al., 2013; Mazzocco et al., 2011b; Starr et al., 2013) with results from studies showing largely the opposite (Bartelet et al., 2014; Fuhs and McNeil, 2013; Kolkman et al., 2013; Sasanguie et al., 2014; Toll and Van Luit, 2014). Indeed, there is even evidence to suggest that developmental influence runs in the opposite direction – that improvement in symbolic number abilities predict later accuracy in nonsymbolic magnitude comparison (Mussolin et al., 2014; see also Gelman and Gallistel, 2004). It may be that taking a broader view of how the key neural systems of young children change as a function of math education and math learning can provide crucial insight into this debate.

Number or Magnitude?

At this point, the reader may have noticed that I have used the term 'magnitude' when discussing the capacity to process approximate, nonverbal, perceptual, and nonsymbolic numbers or quantities. In recent years, the phrase 'approximate number system' (ANS) has appeared as an appellation for one's capacity to perform many of the nonsymbolic tasks described above (e.g., Halberda et al., 2006; Butterworth, 2010; Cantlon et al., 2009; McCrink and Spelke, 2010; Piazza, 2010). References to the ANS have become common in the literature; however, this has not occurred without some controversy. First, the scope of the term is not entirely clear, as it has been used refer to a range of tasks which are perhaps less consistently related to one another than might be expected if all relied upon a singular and unitary underlying construct (Gilmore et al., 2011; Inglis and Gilmore, 2014; though see also Price et al., 2012). Second, there remains some question as to whether what is being measured by these nonsymbolic tasks is indeed *numerical*.

This latter point of controversy is driven less by conflicting results than by a fundamental measurement limit: it is geometrically impossible to make all nonnumerical parameters strictly uncorrelated with number in a single trial. Take, for example, a nonsymbolic comparison task. On a given trial, one will see two dot arrays, usually arranged side-by-side. The task is to determine which array contains more items. Here, 'number' is conceptualized as the sum of the discrete items in a given array, and this is contrasted with continuous visual properties of the stimulus, such as individual dot size (area), the total area of all dots in a given array, the local spacing (Euclidean distance) between individual dots, global spacing (e.g., the average pairwise distance between all pairs of dots in the array – a property closely related to density), the outer contour length of the array (a semisubjective tracing of the outer envelope of the array), and so on. In contrast to a discrete conception of number, these properties vary continuously (akin to how the amount of water in a glass varies continuously, at least to the unaided human eye), and hence are typically labeled as 'magnitudes' as opposed to numbers. Notice that most of

these properties will tend to be correlated (or sometimes anticorrelated) with the relative number of dots in each array; that is, these continuous properties provide information about relative number. Hence, decisions may be made not on the basis of the number of items in each array, but may instead be driven entirely or in part by one or more of these covariate, continuous parameters. For instance, if the size of the individual dots is held constant, the array with a greater total area must contain more dots; if total area is equated across arrays, then the array with smaller dots on average must contain more dots. Analogous trade-offs present themselves for the other continuous properties as well. In sum, the very rules of geometry preclude the construction of a pair of arrays that differ in number of items and are exactly equal on all conceivable continuous (nonnumerical) parameters. The question, then, is, if we have no way to measure number independently of these other confounding variables, then can we ever be certain that what we are calling 'approximate number' is numerical at all? Might it be more appropriate to refer to an 'approximate magnitude system'? Indeed, one may question the logical soundness of an 'approximate number' to begin with, in that one may simply be confusing a property of a set (the number of items in the set) with the set's capacity for change (i.e., the possibility for the set to contain different numbers of objects with different probabilities). Indeed, this distinction is crucial for understanding and maintaining the difference between a number (even a number expressed as a ratio or proportion) and a probability. To be sure, debate is heated (e.g., Cordes and Brannon, 2009; De Hevia, 2011; Gebuis and Reynvoet, 2012a,b,c; Leibovich and Henik, 2013, 2014; Nys and Content, 2012); however, as has happened elsewhere when scientists have run up against what appears to be a fundamental limit on humans' capacity to measure a given phenomenon, one's ultimate conclusion may well be more a matter of philosophy (Heisenberg, 1979).

In sum, then, whether one chooses to refer to an 'ANS,' an 'approximate magnitude system,' 'number sense,' or simply 'nonsymbolic magnitude processing' may, at least at present, be largely a matter of opinion. Given the ongoing controversy, for present purposes, I have chosen what seems to me the most neutral term – nonsymbolic magnitude processing. However, the reader is encouraged to recognize these other terms in the literature, and, hopefully, consider the theoretical assumptions behind each.

Subitizing

As noted in the previous section, there is a certain conceptual difficulty (and perhaps methodological indeterminacy) with the notion of 'approximate number.' If one's requirement for nonsymbolic 'number' is that the numerical representation be exact, then one possible candidate is subitizing. Subitizing refers to the rapid, exact apprehension of the number of objects in a set without explicit counting (Mandler and Shebo, 1982; Dehaene and Cohen, 1994; Trick and Pylyshyn, 1994). Subitizing is subject to a limit of about four items that appear to be tied to a general processing capacity limit for visual short-term memory (Luck and Vogel, 1997; Piazza et al., 2011). When enumerating the exact number of objects in a set, when there are four or fewer, performance varies very little for sets with one versus four objects (both in terms of errors and response times; e.g., Trick and Pylyshyn; Revkin et al., 2008; Vuokko et al., 2013; Watson et al., 2007). This stands in contrast to enumerating larger sets of objects. One either begins to introduce increasingly large errors as the number of items increases (in the case of estimation; e.g., Revkin et al., 2008; Izard and Dehaene, 2008), or response times systematically increase as one counts the additional items (e.g., Trick and Pylyshyn, 1994; Vuokko et al., 2013). Furthermore, counting appears to rely disproportionately more on working memory resources than does subitizing (Shimomura and Kumada, 2011; Tuholski et al., 2001). Neuroimaging evidence also supports the notion that processing nonsymbolic sets >4 relies on qualitatively different neural systems than does processing subitizable set ≤ 4 (Ansari et al., 2007; Ester et al., 2012; Sathian et al., 1999; Vetter et al., 2011; Vuokko et al., 2013). There is also evidence to suggest there are two separate systems for processing small (≤ 4) and large (>4) numbers of items even in infants (Xu and Spelke, 2000). Taken together, there is evidence to suggest that subitizing operates in a qualitatively different manner than processing of larger nonsymbolic magnitudes. One important upshot (to which I will return in the next Section Symbolic Numbers) is that representation of exact number appears to be possible in the case of subitizing, even in young children (Le Corre and Carey, 2007).

Symbolic Numbers

Symbolic numbers are a relatively recent cultural invention when viewed from the broader context of human evolution. There is some evidence to suggest that tally sticks were used to record quantities perhaps as early as 40 000 years ago (Ifrah, 2000). However, evidence for more sophisticated systems for representing and manipulating abstract numerical symbols is absent from the archaeological record until the rise of Mesopotamian civilization around 3100 BC, which was followed shortly thereafter by the emergence of symbolic number systems in ancient Egypt and China only a few centuries later (Ifrah, 2000). Archaeological evidence for the use of spoken number words – another kind of number symbol – is more difficult to come by, though one may infer their use, for example, from root languages such as Proto-Indo-European (PIE). Many languages that have descended from PIE share similar forms for number words up to about 10 (Menninger, 1969/1992). As PIE is believed to have been originally spoken *c*.4200 BC (Blench and Spriggs, 1997), one may infer the use of similar number words perhaps as early as roughly 6000 years ago. On the other hand, present-day indigenous cultures without substantial contact with modern developed cultures have number words up to only three or four, and they lack more sophisticated means of computing exact quantities that exceed this limited range (Pica et al., 2004). In sum, while the ability to process nonsymbolic magnitudes appears to stem from a deep evolutionary history, the ability to manipulate exact numbers in symbolic

form is a much more recent cultural invention (see also Damerow, 2001). This places the acquisition and mastery of even basic processing of symbolic numbers (such as memorization and linking of simple arithmetic facts) at a fascinating junction between evolution and culture (Dehaene and Cohen, 2007; Ansari, 2008).

Symbol Grounding

A central question for research on symbolic numbers concerns what exactly number symbols represent – what do they refer? (Harnad, 1990). An early proposal is that they refer to the corresponding nonsymbolic magnitude: "When we learn number symbols, we simply attach their arbitrary shapes to the relevant nonsymbolic quantity representations" (Dehaene, 2008: p. 552; see also, Dehaene, 1997; Gallistel and Gelman, 2000). The appeal of this explanation is clear: the meaning of a symbolic number is grounded in what appears to be its evolutionary precursor in the (possibly innate) representation of the corresponding nonsymbolic magnitude, and support for this view has been echoed many times over (e.g., Verguts and Fias, 2004; Feigenson et al., 2004, 2013; Piazza et al., 2007; Hubbard et al., 2008; Libertus and Brannon, 2009; Nieder and Dehaene, 2009; Lyons and Ansari, 2009; Eger et al., 2009). More specifically, the argument is that symbolic numbers provide a more precise mapping (narrower tuning curve) onto the corresponding nonsymbolic magnitude (for a computational instantiation of this view, see Verguts and Fias, 2004).

Three different lines of evidence are often cited to support the proposal that symbolic numbers' meaning is derived from direct reference to their corresponding nonsymbolic magnitude. First, numerical signatures such as the distance and ratio effect show qualitatively similar patterns for symbolic numbers and nonsymbolic magnitudes (e.g., Buckley and Gillman, 1974; Dehaene, 2008). Second, neuroimaging evidence often points to similar neural substrates – specifically, the IPS – for symbolic and nonsymbolic number processing (Fias et al., 2003; Diester and Nieder, 2007; Piazza et al., 2007; Eger et al., 2009). Third, individual differences in nonsymbolic magnitude processing are related to more complex symbolic math abilities (as reviewed in the previous Section Number Sense in Early Development). In sum, one candidate for the meaning of a symbolic numbers – i.e., a potential solution to the symbol grounding problem – is that a given symbol simply refers to one's internal representation of the corresponding nonsymbolic magnitude.

Recently, several counterarguments to this proposal have arisen. First, one may note that distance effects are observed in virtually any discrimination task, whether one is distinguishing between items on the basis of perceptual dimensions (e.g., odor discrimination in drosophila; Parnas et al., 2013) or more abstract, categorical variables (e.g., distinguishing between species of animal figures; Gilbert et al., 2008). As discussed previously when interpreting distance and ratio effects, it is difficult to see how these effects in symbolic numbers are indicative of underlying representations in the same way as nonsymbolic magnitudes. Hence, it may be just as problematic to argue that qualitatively similar numerical distance/ratio effects are evidence of common representation across symbolic numbers and nonsymbolic magnitudes as it would be to argue that odors in drosophila and abstract animal categories in humans are underlain by a common representation.

Second, with respect to neural overlap of symbolic and nonsymbolic number processing, inferring a common neural mechanism from coactivation of brain regions (called reverse inference), though common, is logically problematic (Poldrack, 2006). Recent evidence suggests that such overlap in the case of numbers is dependent upon task demands in any case: neural activity for symbolic and nonsymbolic numerical ordering tasks shows a qualitatively different pattern of overlap relative to that for symbolic and nonsymbolic numerical comparison tasks (Lyons and Beilock, 2013). Further, of the three papers (Eger et al., 2009; Damarla and Just, 2013; Bulthé et al., 2014) that assessed whether distributed patterns of activity during processing of numbers in one format (e.g., symbolic) can be used to decode processing of numbers in the opposite format (e.g., nonsymbolic), only one (Eger et al., 2009) found evidence of successful cross-format decoding (and even in that case decoding was unidirectional and only slightly above chance: 57% accuracy, where chance was 50%). Cross-format fMRI adaptation has also yielded mixed results, with the responses to format change substantially larger than the responses to number change (Cohen Kadosh et al., 2011; though see also Piazza et al., 2007). In sum, while it is certainly possible that neural overlap of symbolic numbers and nonsymbolic magnitudes is more than a coincidence (Dehaene and Cohen, 2007), closer inspection suggests that there is substantial neural dissociation between the two formats. Behavioral evidence is consistent with this view: when asked to directly compare a symbolic number with a nonsymbolic magnitude (in an otherwise standard number comparison task), the cost of switching between formats is closer to what one would expect if the two formats referenced different as opposed to the same underlying representations (Lyons et al., 2012).

Third, with respect to the relationship between nonsymbolic magnitude processing and more complex math skills, as discussed in the previous Section Number Sense in Early Development, evidence for this result is quite mixed, even in preschoolers and kindergarteners who are just learning to use symbolic numbers. In sum, then, recent evidence has begun to erode a strong view of the notion that the meanings of number symbols are grounded in a direct reference to their nonsymbolic counterparts. An alternative explanation is that number symbols are initially linked exclusively via the exact, nonsymbolic quantities within the subitizing range (≤ 4; Carey, 2004). Indeed, Le Corre and Carey (2007) showed that 3- and 4-year-old children mapped number words onto corresponding magnitudes within the subitizing range prior to acquiring an understanding of the 'cardinality principle' (that counting to any number yields the number in the set, as indexed as the last number said). Children at this age failed to consistently map corresponding number words onto sets containing more than four items until several months after acquiring the cardinality principle. Further evidence consistent with this view has been found in adults: the cost of

mixing symbolic and nonsymbolic formats for small numbers (≤4) is substantially smaller than that found for large numbers (>4; Lyons et al., 2012), suggesting that subitizable symbolic and nonsymbolic numbers may retain a strong link even into adulthood.

Beyond Number Sense

How, then, do number symbols outside the subitizing range acquire meaning? One idea is that, having established a one-to-one mapping with nonsymbolic subitizable magnitudes, the meaning of (numerically) larger symbolic numbers are then bootstrapped from the smaller number symbols (Carey, 2004). Precisely how this process occurs, however, remains a point of debate (Ansari, 2008). One proposal is that the grammatical structure of language plays a critical role in inferring the existence and later the meaning of large exact numbers (Carey, 2004; Le Corre and Carey, 2007; Almoammer et al., 2013; Sarnecka et al., 2007; Sullivan and Barner, 2014). Another possibility is that mapping symbolic numbers to a visual-spatial mental number line is key (e.g., Gunderson et al., 2012). Specifically, understanding that the numerical distance between integers remains constant helps one to apprehend the notion of large exact numbers, which is evidenced by a linearization of the number line up to ever-increasing magnitudes (10, 100, 1000, etc.; Siegler and Ramani, 2008). Yet another view suggests that how we understand numbers as ordered sequences differs fundamentally between symbolic and nonsymbolic numbers (Lyons and Beilock, 2011, 2013). The ordinal associations between symbolic numbers may thus provide one distinct aspect of symbolic numbers' respective meaning (Nieder, 2009). These competing views need not be mutually exclusive, and indeed, they all share the general assumption that the meanings of larger number symbols do not remain directly tied to their nonsymbolic counterpart. (For a competing view that expressly disagrees with this assumption, see Feigenson et al. (2013).) Note that this assumption is consistent with a broader view of symbolic representation more generally (Deacon, 1997; for an early suggestion applying this perspective specifically to number representation, see Nieder, 2009). According to this view, it is the relations between symbols that ultimately come to define a symbolic system. Over time, these relations may even come to overshadow each symbol's link to an external referent. It is perhaps this that makes it possible to manipulate very large numbers such as 1 000 000 without having a concrete sense of what 1 000 000 is like. That said, even if such a view proves to be correct, a major unanswered question concerns the precise mechanism – whether that be linguistic, visual-spatial, ordinal, nonsymbolic magnitudes, some combination thereof, or something else entirely – that links number symbols to one another. Answering this question is thus a major contemporary topic of research in the field of numerical cognition. On a somewhat grander scale, such research can help us understand how cultural and evolutionary forces interact within the human brain in shaping our ability to manipulate the world of and with mathematics.

Abstract

A 'number system' consists of a set of mental entities and operations together with systems of symbols and symbolic activities. Until recently, cultures existed without any arithmetical techniques. The occurrence of the simplest genuine arithmetical activities dates back to the Late Neolithic and the Early Bronze Age. Advanced number systems evolved with the rise of early civilizations and the invention of writing. Context-dependent numerical sign systems were used to solve the administrative problems of early state organization. The later emergence of an abstract concept of number was a consequence of cultural exchange in the Hellenistic and Roman world. Limitations of this early number concept resulted from the introduction of algebraic notations, leading to the formalistic approach of the nineteenth century. Formalism finally eliminated in the twentieth century the conceptual distinction between number systems and other mathematical objects.

The Term 'Number System'

A 'number system' consists of a set of mental entities and operations together with systems of symbols such as number words, tallies, or numerical sign systems and of symbolic activities such as counting, addition, or multiplication representing them. Number systems evolved in the course of the development of most civilizations. This evolution changed not only numbers and number representations but also the meaning of the term 'number' itself.

Symbolic activities such as counting, the use of tallies for representing quantities, or performing calculations by means of tokens or systems of written symbols, are usually considered practices dealing with 'numbers.' However, such symbolic activities historically precede an explicit number concept. Explicit concepts of number are the outgrowth of reflection upon such activities.

When first explicit concepts of abstract 'numbers' emerged in history, they were restricted to the number system which is called today 'natural numbers,' that is, to the system '1, 2, 3, 4, …' The subsequent history of the term number is characterized by a series of extensions of the number concept to cover 'integers,' 'rational numbers,' 'real numbers,' 'complex numbers,' 'algebraic numbers,' and other mathematical objects designated, with lesser or greater justification, as a number system. These extensions usually included numbers of earlier stages as special kinds of numbers, but necessarily also dismissed certain properties which seemed to be essential in earlier stages. Consequently, any extension of number systems was accompanied by controversial discussions about the question whether the newly-considered mathematical objects were really numbers. These doubts are often reflected in the designation of such numbers as 'irrational,' 'negative,' 'imaginary,' etc. Finally, the variety of potential candidates for the term number became so great that the answer to the question of what is and what is not a 'number' turned into a merely conventional decision. The focus of attention shifted from the investigation of types of numbers as they were historically determined towards the study of their common structures.

Cultures without Number Systems

Until recently, 'prearithmetical' cultures existed without any arithmetical techniques at all such as finger counting, counting notches, counting knots, or tokens. The best known examples are the Australian aborigines (Blake, 1981; Dixon, 1980) and certain South American natives (Closs, 1986) whose languages did possess terms for quantities, yet of an exclusively qualitative nature, terms such as 'many,' 'high,' 'big,' or 'wide' (*see* Australian Aboriginal Society and Culture: An Overview; Justice: Philosophical Aspects; South America: Sociocultural Aspects). The quantitative aspects of an object of cognition were not yet distinguished from its specific physical appearance (*see* Indigenous Knowledge: Science and Technology Studies). Since from periods before the Late Neolithic no objects or signs have been identified that might have had some kind of arithmetical function, it is likely that up to that time human culture remained entirely prearithmetical. While artifacts with repeated signs and regular patterns from periods as early as the Late Paleolithic (*see* Modernity: Anthropological Aspects) have occasionally been interpreted as representations of numbers (Marshack, 1972), such an interpretation seems to be untenable since these sign repetitions lack the characteristic subdivision by counting levels which is present in all real counting systems (Damerow, 1998).

Proto-Arithmetic

The occurrence of the simplest genuine arithmetical activities known from recent nonliterate cultures (see, e.g., Saxe, 1982) date back to the Late Neolithic and the Early Bronze Age. These activities aiming at the identification and control of quantities are based on structured and standardized systems of symbols representing objects (*see* North America: Sociocultural

[†] Deceased.

Aspects; Ritual and Symbolism, Archaeology of). Their emergence as counting and tallying techniques may have been a consequence of sedentariness. Symbols are the most simple tools for the construction of one-to-one correspondences in counting and tallying that can be transmitted from generation to generation. The organization of agricultural cultivation, animal husbandry and household administration led to social conditions that apparently made symbolic techniques useful, and their systematic transmission and development possible. Such techniques are 'proto-arithmetical' insofar as the symbols represent objects and not 'numbers,' and consequently are not used for symbolic transformations which correspond to such arithmetical operations as addition and multiplication.

Early explorers and travelers encountering indigenous cultures using proto-arithmetical techniques often anachronistically interpreted their activities from a modern numerical perspective and believed the limitations of proto-arithmetic resulted from deficient mental abilities of such peoples. It was only in the first half of the twentieth century that anthropologists and psychologists challenged these beliefs (e.g., *see* Klein, Melanie (1882–1960); Boas, Franz (1858–1942)) and began seriously to study culturally specific mental constructions connected with proto-arithmetical activities (Levy-Bruhl, 1923; Wertheimer, 1925).

From Proto-Arithmetic to Systems of Numerical Symbols

A further step in the evolution of number systems resulted from the rise of early civilizations and the invention of writing. This transition is particularly well documented in the case of the Ancient Near East (*see* Writing, Evolution of). A system of clay tokens possessing proto-arithmetical functions has been identified which may have been widely used already during the period from the beginning of sedentariness in the areas surrounding the Mesopotamian lowland plain and in the Nile valley around 8000 BC until the emergence of cities around 4000 BC (Schmandt-Besserat, 1992).

In the fourth millennium BC this proto-arithmetic system of clay tokens became the central tool for the control of a locally-centralized economic administration. In order to serve this purpose, the proto-arithmetical capabilities of the system were exploited to the limits of their capacity. The safekeeping of tokens in closed and sealed spherical clay envelopes demonstrates that they were used for the encoding of important information. The tokens were complemented and later completely replaced by markings that were impressed on the surface of such clay envelopes or on the surface of sealed clay tablets. Thus, the system was transformed into a more suitable medium by substituting written signs for tokens. Around 3200 BC, the numerical notations were supplemented with pictograms, and the tablets achieved a more complex structure. They now displayed several quantitative notations arranged according to their function, as we find in an administrative form. The earliest attestation of addition as an operation with symbols is provided by the notation of totals of the entries on such tablets, usually inscribed on the reverse of the tablet containing these entries.

Based on their origin, the oldest written numerical notation systems exhibited, for a short period, very unusual characteristics. Since they initially still represented units of counting and measurements, and since the numerical relations between these units were dependent on the counted or measured objects, the numerical signs had no uniquely determined values. Their values resulted from their metrological context, and changed with the respective areas of application without any apparent attempt to attain unambiguous numerical values for the signs. From the viewpoint of modern arithmetic, the signs thus represented in different contexts different numbers (Damerow, 1995; Damerow and Englund, 1987). Some 500 years later, however, the system had developed into a sort of numerical sign system as is known from other early civilizations. In particular, the signs had now attained fixed numerical values.

Systems of Numerical Symbols in Early Civilizations

Most, if not all, advanced civilizations, in particular the Egyptian empire, the Mesopotamian city-states, the Mediterranean cultures, the Chinese empire, the Central American cultures, and the Inca culture, have, independent from each other or by adaptation from other cultures, developed systems of numerical symbols that exhibit similar semiotic characteristics. The basic symbols of these systems were the same as at the proto-arithmetical level, signs for units and not for numbers, but since they represented now complex metrologies they had necessarily also to deal with fractions. Furthermore, part of the systems were now complex symbol transformations, that is, arithmetical techniques such as Egyptian calculation using unit fractions (Chace, 1927), sexagesimal arithmetical techniques of the Babylonians (Neugebauer, 1934), transformations of rod numerals on the Chinese counting board (Lǐ and Dù, 1987), calendrical calculations in the pre-Columbian culture of the Maya (Closs, 1986; Thompson, 1960), or techniques of the use of knotted cords *(quipu)* as administrative tools by the Inca (Ascher and Ascher, 1971–1972; Locke, 1923).

The development of these numerical techniques was historically closely related with the administrative problems that had arisen through the concentration of economic goods and services in the governmental centers of early state organization (*see* State: Anthropological Aspects). The dramatic rise in the quantities of products had to be controlled, and the immense variety of decision-making implications had to be executed administratively (Høyrup, 1994; Nissen et al., 1993).

The rules dictating the use of numerical signs reflected this function; they corresponded to their meaning in the social context. The numerical sign systems thus exhibited a great variety of structures with no internal differentiation between rules representing a universal number concept and rules depending on the specific kind of symbolic representation and its function to control quantities in a specific social setting. It was only the cultural exchange between advanced civilizations with developed systems of numerical notations that created the preconditions for the differentiation between universal numbers and specific notations.

The Euclidean Conceptualization of Number

The emergence of an abstract concept of number as a consequence of cultural exchange is particularly well known from the ancient Greek culture which played a crucial role in the historical process of transforming the heritage of early Near Eastern civilizations into the intellectual achievements of the hegemonic cultures of the Hellenistic and Roman world. The reflective restructuring of divergent bodies of knowledge brought about new kinds of general concepts and, in particular, an abstract concept of number (*see* Reflexivity in Anthropology).

The oldest known examples of general propositions about abstract numbers, for instance, the statement that the number of prime numbers is infinite, are handed down to us through the definitions and theorems of Euclid's Elements (Heath, 1956). The relevance of these definitions and theorems was no longer based on their practical applicability, but only on their role within a closed system of mental operations. These operations reflected certain arithmetical activities in the medium of written language. In the case of the number concept these operations were the techniques of counting and tallying. Euclid defined a number as a 'multitude composed of units' and hence restricted the abstract concept of number to natural numbers. Platonism, in particular, dogmatically excluded from theoretical arithmetic all numerical structures that did not come under the Euclidian definition. Fractions of a number, for instance, and even more so irrational numbers such as the square roots of natural numbers that are not squares were not accepted themselves as numbers.

In order to circumvent the problems of incommensurability, a theory of proportions was developed, not for numbers, but for entities designated as 'magnitudes' (Heath, 1956). This theory served at the same time as a substitute for an expanded concept of number that could cover all the arithmetical activities and symbolic operations existing at that time.

At a practical level, however, operations with notations for other types of number systems had been developed and were used long before they were theoretically reflected in an extended number concept. Any exchange of goods by merchants or by administrators of a centralized economy implicitly involves fractions. The balancing of debits and credits in bookkeeping similarly involves negative numbers. Accordingly, arithmetical techniques for dealing implicitly or even explicitly with fractions or with negative and irrational numbers had thus been developed already in early civilizations long before they were reflected in an explicit number concept.

The Impact of Algebra

The problems resulting from the restrictive Greek number concept were aggravated with the renaissance of ancient mathematics in the Early Modern Era. In particular, the development of algebraic notation techniques and of analytical methods applied to continuous processes in mechanics made the distinction between numbers and magnitudes obsolete. The use of variables in order to solve equations was indifferent to this conceptual distinction. Fractions, negative numbers, irrational numbers, infinitesimals, and infinity became more and more accepted as numbers. Although infinitesimals were again expelled in the nineteenth century after their missing logical foundation resulted in serious contradictions in the conceptual system of mathematics, they were finally reintroduced in a new form by the nonstandard analysis of the twentieth century.

The introduction of algebraic notations thus contributed to the transformation of existing arithmetical techniques into conceptualized number systems, but it also initiated the creation of completely new ones. A new type of number system with no immediately obvious meaning emerged, reflecting no longer primary arithmetical techniques but rather abstract operations with variables and equations. A well-known example is provided by 'imaginary' square roots of negative numbers which occurred as solutions to higher degree equations. Such solutions, although calculated correctly according to rules for numbers, seemed to make no sense since squaring a number never results in a negative number. Nevertheless, it turned out to be possible to operate consistently with such imaginary numbers as if indeed they were, in fact, numbers. They were, thus, finally accepted as 'complex numbers.'

The justification of seemingly meaningless number systems was not the only problem posed by the development of mathematics in the nineteenth century. The term number became questionable for other reasons too. On the one hand, a productive new theory, even today called simply 'theory of numbers,' was created; it is, however, a discipline with a specific topic. The term number is in this theory restricted to (positive and negative) integers. On the other hand, a growing number of new types of mathematical systems emerged which, with greater or lesser emphasis, were called number systems, for example, 'algebraic numbers,' 'transcendental numbers,' 'higher order complex numbers,' 'quaternions,' 'biquaternions,' etc. In order to organize the hodgepodge of artificially-constructed number systems, a heuristic principle was formulated. The construction of number systems should follow the 'principle of the permanence of formal laws' of an *arithmetica universalis* (Hankel, 1867), that is, they should be constructed in such a way that some of the rules of ordinary numbers are preserved. It was hoped, in particular, that 'higher order complex numbers' of a certain type might serve as the foundation for an infinite number and virtually all possible number systems, an expectation which later turned out to be misguided.

Formalism and the Decline of Number

The formalistic approach, which in the nineteenth century led to the flourishing number systems and ascribed to them a key role in the foundation of mathematics, reduced their importance in the course of the structuralist rebuilding of mathematics in the twentieth century. In fact, the recombination of structures and operations of mathematical objects in order to create new ones with new properties made it more and more difficult to distinguish number systems from other systems of mathematical objects. The designation of an object as

a number was increasingly seen as merely an historical convention. Number systems were downgraded to instances of structures abstracted from them, in particular, of algebraic structures resembling addition and multiplication and topological structures determining distance and continuity. Not numbers, but 'sets' equipped with such structures, which were designated artificially as 'groups,' 'fields,' 'rings,' 'lattices,' 'compact spaces,' etc., became the building blocks of modern mathematics.

Abstract

In this article we first trace the origins of Milgram's obedience studies in classic suggestion research and in the conformity studies of Solomon Asch. The basic Milgram paradigm is outlined, with particular emphasis on the so-called 'new baseline' condition. The findings in this and other conditions – which range from 0% to 100% obedience – are described. We then look at Milgram's rich speculations about the processes involved, which can be found in his experimental notebooks, archived at Yale University. We contrast this with the 'agentic state' explanation which Milgram later used to explain his findings. We also critique this explanation, showing that it cannot account for variations in obedience between conditions, nor the points at which people are most likely to disobey within conditions. We argue that its inadequacy lies in taking the relationship between experimenter and participant for granted, hence ignoring both when and how it is established. Drawing on some of Milgram's early speculations, we advance an 'engaged follower' perspective which explains obedience in terms of the identification of participants with the science of the study and with the experimenter as a representative of that science. We conclude by using this perspective to bring together both scientific and ethical dimensions of the Milgram's obedience studies.

More than any other topic in social psychology, perhaps, the study of obedience is dominated by one researcher – Stanley Milgram – and by one piece of research – his aptly named Yale Obedience Studies. To cite Muzafer Sherif "Milgram's obedience experiment is the single greatest contribution to human knowledge ever made by the field of social psychology, perhaps psychology in general" (cited in Takooshian, 2000, p. 10). But one underestimates Milgram's significance if one limits one's focus to the discipline of psychology. He has had considerable impact across a range of disciplines from sociology to theology, from history to law. And his influence goes far beyond the academy. It has marked popular culture. Milgram's work has been disseminated through television documentaries, theater plays, art shows, and even a film – *The Tenth Level* – in which Star Trek's Captain Kirk (William Shatner) plays a fictionalized Milgram. Moreover, as Peter Novick documents, since the 1960s Milgram's ideas have been "invoked in discussing everything from the Vietnam War to the tobacco industry, and, of course, reflecting back on discussions of the Holocaust" (2000, p. 137).

The link to the Holocaust is not coincidental. For Milgram's interest in, and research on, issues of obedience, was clearly rooted in his own experiences as the child of Jewish parents of East European origins, growing up in the United States during the World War II, acutely concerned as news of the unfolding tragedy filtered through. At his Bar-Mitzvah in 1946, he said "As I come of age and find happiness in joining the ranks of Israel, the knowledge of the tragic suffering of my fellow Jews throughout war-torn Europe makes this also a solemn event and an occasion to reflect upon the heritage of my people – which now becomes mine" (cited in Blass, 2004, p. 8).

Through his life, Milgram continued to reflect on this heritage and how it came to pass. His early research drew on the famous conformity studies of Solomon Asch, which in turn drew on a tradition of 'suggestion' research which goes back to the prehistory of social psychology (see Asch, 1955). In the late nineteenth century, specifically in France, researchers became increasingly interested in hypnotism, first as a means of diagnosing those 'hysterics' who were particularly prone to ideas implanted by others, later as a model of social functioning in general (see Barrows, 1981; Goldstein, 1982). This idea came to a head in the work of Gabriel Tarde who famously remarked that "la societe, c'est l'imitation, et l'imitation, c'est une espece de somnambulisme" (society is imitation and imitation is a form of somnambulism; Tarde, 1901, p. 95). (Translation by the authors. Note that Asch, in his 1955 paper, uses a variant of this quote: "social man is a somnambulist.") The idea, then, is that, especially when immersed in large groups with others, people cannot help but conform to the prevailing opinion.

Asch's aim was to investigate this idea of group pressure more closely and more systematically. Unlike previous studies, which had largely studied social opinions or aesthetic judgments, he addressed whether people would alter their judgments of physical stimuli (the length of a line) when confronted with the views of others. Asked to match one of several options with a target line, fully 76% of participants chose the wrong option at least once when it had previously been selected by other respondents (who were actually confederates of the experimenter). Overall, participants accepted the majority's false judgment on just over a third of the trials (36.8% to be precise; see Asch, 1955). As Jetten and Hornsey (2012) document, Asch himself provided a nuanced analysis

of his findings. On the one hand he bemoaned the fact that the tendency toward conformity is so strong that intelligent people can be led to call white, black. On the other hand, he stressed that we should not underestimate the human capacity for nonconformity. That is, however striking and surprising one-third of the responses where people went along with the confederates might be, we must not let them obscure the two-thirds of responses where they did not. To cite Asch himself "anyone inclined to draw too pessimistic conclusions from this report would do well to remind himself that the capacities for independence are not to be underestimated" (1955, p. 35).

Over time, however, Asch's caveats have been forgotten and the accounts of his studies have increasingly laid a one-sided stress on conformity over independence. Indeed, we shall see that this 'conformity bias' (Moscovici, 1976) is more general in social psychology and indeed leads to an equally one-sided account of Milgram's findings. But this is to get ahead of ourselves. For now, it is important to trace the passage from Asch's conformity studies to Milgram's obedience studies.

At first Milgram was interested in whether one could find national differences in the level of conformity. Would some conform more than others? But he remained dissatisfied with the basic paradigm itself. While the general phenomenon of conformity seemed important and relevant to societal phenomena, this was undermined by the fact that the topic of conformity – line judgments – seemed so trivial and so distant from events like the Holocaust (Blass, 2004). He began to ask whether people would conform when it came to more significant behaviors, like aggressing against another person. Moreover, would they do so if one substituted Asch's group of confederates for a single figure of authority? Putting these two things together, Milgram came up with the question: Just how far would a person go under the experimenter's order? That was the point where the obedience studies were born. Milgram later remarked "it was an incandescent moment" (cited in Blass, 2004, p. 62).

The Obedience Studies

If Milgram's obedience studies – or, at least, certain aspects of them – are exceedingly well known, the extensive efforts that Milgram spent in gradually shaping the paradigm in order to make it work smoothly is far less familiar. The basic outline of the studies was determined fairly early on. A participant would come along to the laboratory, ostensibly to take part in a learning experiment. Once there he (there was one study using women, but the great majority of respondents were male) would be greeted by the experimenter, allocated to the role of 'teacher' and instructed to administer an ascending series of electric shocks each time the learner (actually an actor who was a confederate of Milgram) made an error on the learning task. But beyond that, everything remained to be settled: how would the experimenter behave and how would he urge the participant on?; how would the participant be persuaded that real shocks were being administered?; how would the learner react as the shock level went up?

To start with, Milgram went to great lengths to choose an experimenter whom he considered to be sufficiently authoritative. He eventually settled on John Williams, "'a stern, intellectual looking man' who played his experimenter's 'role in a cold austere manner'" (from Milgram's notes, cited in Russell, 2011, p. 160). He carefully crafted an elaborate script in which the experimenter introduces the study, explains its scientific importance and its scientific originality. At one critical juncture the script reads "actually, we know *very little* about the effect of punishment on learning, because almost no truly scientific studies of it have been made in human beings" (Milgram, n.d., emphasis and capitals as in the original). He even crafted the things the experimenter should say in case participants seemed reluctant to continue giving shocks. There were four so-called 'prods' to be delivered in sequence: Prod 1 "Please continue"; Prod 2 "The experiment requires that you continue"; Prod 3 "It is absolutely essential that you continue"; Prod 4 "You have no other choice, you must go on" (Milgram, 1974, p. 21). Only if the participant continued to resist after the fourth prod would the session be terminated. (It should be noted, however, that the experimenter did not always stick strictly to the script and even employed impromptu devices – such as pretending to check up on the learner and confirming that he was alright – in order to persuade participants to continue (see Gibson, 2013).)

Milgram also devoted considerable attention to crafting his famous shock generator which now is kept at the Center for the History of Psychology at Akron University in Ohio. As Russell (2011) reveals, early prototypes had 12 switches increasing in 30-V steps from 0 V to 330 V, each with verbal labels attached, the final one initially reading 'LETHAL,' later changed to 'Extreme Shock: Danger.' The final version changed from 12 to 30 switches, increasing in 15-V steps up to a maximum of 450 V, the extreme now labeled with an ambiguous but ominous XXX (see Milgram, 1974, p. 28). Milgram was particularly concerned with making the machine seem impressive and professional. He was particularly delighted when "two electrical engineers examined the instrument and failed to realize it was a simulated device" (Russell, 2011, p. 157).

Finally, Milgram paid as much attention to choosing and scripting the 'learner' as he did the experimenter. His choice of who would play this role had less to do with experience – James McDonough, the successful candidate "probably could not act face-to-face," wrote Milgram (cited in Russell, 2011, p. 159) – than with his demeanor. Milgram thought McDonough to be "perfect as a victim" because he was "mild and submissive; not at all academic" (Russell, 2011, p. 159).

In early variants of the study, the learner said and did very little as the shocks were administered. Indeed, it appears that, in some of the initial pilot studies, nothing at all was heard from the learner as the shocks were delivered and here all the participants went up to the 450-V maximum – although it appears that Milgram thought this was atypical and reflected the nature of the Yale students ('Yalies') who had served as participants (A. Milgram, 2000). Henceforth he would use a broad cross section of the (mainly male) population in his studies. In the first of the published studies (Study 1 in Milgram's, 1974 summary of his work, called the 'Remote' condition), the learner, who was in a separate room to the participant, was restricted to banging on the wall at 300 V and then ceasing to respond after 315 V. All participants went up to the 300-V mark and 65% continued to 450 V.

The feedback became more elaborate in Study 2, the 'Voice-feedback' condition). Now the complaints of the learner could be heard clearly through the wall. Groaning would start at 75 V. At 150 V the learner would demand repeatedly "Let me out of here." The groans, screams, and demands would increase until, at 300 V the learner exclaimed "You can't hold me here," and, at 315 V, "I'm no longer part of this experiment." After the 330-V mark, he would fall silent and stop responding in any way.

This variant has sometimes been called the 'Baseline condition' and it elicited similar levels of total obedience to Study 1 (62.5% vs 65%), although here, people start to drop out much earlier (from 135 V). Further small amendments were made for Study 5, which Milgram terms the 'New baseline condition' in his 1974 book *Obedience to Authority*, but which (for reasons that will soon become clear) he originally dubbed the 'Coronary condition.' This is the best known of Milgram's studies, the one which generally appears in text books, and often the only condition that is mentioned when Milgram's studies are discussed. The full script is reproduced in *Obedience to Authority* (pp. 56–57) and it differs from Study 2 only in that, at various critical junctures (the 150, 195, and 330-V points), the learner refers to the fact that he has a heart condition. For instance, at 150 V the learner exclaims "Ugh!!! Experimenter! That's all. I told you I had heart trouble. My heart's starting to bother me now. Get me out of here please. My heart's starting to bother me. I refuse to go on. Let me out" (Milgram, 1974, p. 56). But still, 65% of participants carry on to the 450-V endpoint.

These results came as a major surprise. A large proportion of ordinary Americans, like Yale students it seemed, were willing to administer potentially lethal electric shocks to people simply because they had made errors on a learning task. This was completely at odds to how ordinary Americans thought that they would act. When he asked a sample of 110 people how they themselves would respond – a mixture of professionals, students, and middle-class adults – none thought they would go beyond 300 V and the mean point at which people thought they would break off was between 120 V and 135 V (whereas only 1 out of the 40 participants in the 'New baseline' condition stopped before 150 V). Moreover, the actual behavior was also completely at odds with the way that psychiatric professionals estimated that ordinary people would act. They predicted that most people would not go beyond 150 V and that only 0.125% – the pathological fringe – would go on to the end. Milgram appeared to have discovered a surprising and uncomfortable truth about human behavior. How could it be explained?

Explaining Obedience

In his early writings, Milgram wrestled long and hard with the significance of his findings. For instance, in his first published account of the research in 1963, Milgram lists 13 possible factors of significance: the reputation of Yale University where the research took place; the fact that the research is ostensibly about advancing a worthy purpose – how to help people learn; the way in which people voluntarily make a commitment to participate in the research; the ambiguity about the prerogatives of the experimenter and the rights of the learner; and so on.

Over time, however, Milgram's position changed. Even though his 1974 book mentions some of the possibilities that appear in the early writings, these are overshadowed by another explanation. This is the idea that, in the face of authority, people slip into an 'agentic state.' This term denotes the idea that people cease to act in terms of their own purposes and instead act as an agent for someone else's. In everyday terms "(t)he ordinary person who shocked the victim did so out of a sense of obligation – a conception of his duties as a subject – and not from any peculiarly aggressive tendencies" (Milgram, 1974, p. 6). Once in this state, people are so focused on how well they do the bidding of that authority that they lose concern for all else. In particular, they have little interest in the consequences of their actions and the plight of their victims. Essentially, they become bureaucratic zombies. They are able to commit harm largely because they do not think about what they are doing.

In formulating the concept of the agentic state, Milgram drew heavily on the ideas of Hannah Arendt. Arendt famously observed the trial of Adolf Eichmann in Jerusalem (which, coincidentally, took place at the exact same time as Milgram was conducting his obedience studies in 1961). Like all the others waiting in the courtroom, Arendt assumed that this man – the chief bureaucrat of the Holocaust – would appear monstrous. But what they saw was a seemingly insignificant character, middle-aged and balding, slightly hunched, fastidiously taking notes on the proceedings. Eichmann, she concluded, committed the most horrendous acts for the most banal of reasons – to please his superiors. "Eichmann," she says, "had no motives at all. He merely, to put the matter colloquially, never realized what he was doing" (Arendt, 1963/1994, p. 287).

Arendt summed the lesson that she drew from this in a ringing phrase "the lesson of the word-and-thought-defying banality of evil" (Arendt, 1963/1994, p. 252). Milgram concurred. Immediately before introducing his own definition of the 'agentic state' (cited above) he observed that "After witnessing hundreds of ordinary people submit to the authority in our own experiments, I must conclude that Arendt's conception of the banality of evil comes closer to the truth than one might dare imagine" (1974, p. 6).

The combination of Arendt's and Milgram's analysis has proved remarkably powerful and extremely resilient. The historical and psychological threads, wound together, provided a far more authoritative account than either could alone. They seemed to define something fundamental about human nature that could explain many, if not all, instances of toxic conformity.

Questioning the 'Agentic State'

In recent years, the 'banality of evil' account has come under increasing fire from historians of the Holocaust. They point out that Eichmann and his ilk, far from being passive 'desk murderers' who had little insight into the realities of mass murder, knew exactly what they were doing, believed in what they were doing, and worked independently and creatively to deport then massacre their victims. These were true Nazi believers who saw Jews as an enemy which had to be exterminated (e.g., Cesarani, 2004; Lozowick, 2002; Stangneth, 2014).

How did Arendt miss this? Vetlesen (2005) argues that, at his trial, Eichmann put on a deliberate act to undermine the prosecution case that he was a distinctively cruel individual. Vetlesen suggests that, in characterizing Eichmann as 'merely thoughtless,' Arendt "adopts the very self-presentation he cultivated" (p. 5).

Equally, Milgram's agentic state account has received mounting criticism from psychologists, even among his admirers (Blass, 2004). Indeed Darley goes so far as to say that "I was startled and appalled by… the odd and pseudoscientific/pseudophysiological concept of the agentic state" (1992, p. 207). In addition to the problem of positing a distinct mental state, which Darley alludes to here, there are two other fundamental problems with Milgram's account. The first is that it simply cannot account for the different levels of obedience that were observed in different variants of Milgram's paradigm. As we have already noted, in these, between 0% and 100% of participants were willing to go to the 450-V mark. But why would there be this variability if there is a general tendency for people to slip into an agentic state in the face of authority?

Giving Milgram the benefit of the doubt, one could treat the agentic state as a continuum and argue that obedience will be higher the more that authority imposes itself upon us. But there is no evidence for this. Thus, focusing on the perceptions of the participant, Mantell and Panzarella (1976) found no relationship between obedience and the extent to which people handed over responsibility for their actions. Equally, focusing on the actions of the experimenter, there is (if anything) a negative relationship between the amount of authority exerted by the experimenter and the degree of obedience. This is evident when one looks at the effects of the different prods that were used to urge on reluctant participants. Recall that only one of these, the fourth prod, was a direct assertion of authority ('You have no other choice, you must go on'), the others are more like requests or justifications. But examples used in Milgram's book suggest that Prod 4 was generally unsuccessful. In one oft-cited example (1974, p. 28), the participant, a Professor of Old Testament Liturgy responds by saying "If this were Russia maybe, but not in America." What is more, a recent replication of the Milgram studies (with the sole difference that participants only went as far as the 150-V point), participants refused to continue *every time* Prod 4 was used (Burger, 2009). Whatever the studies do show, then, it is emphatically not that people always follow orders, no matter how severe.

Moving on, the second fundamental problem with the agentic state account is that it reduces the richness of the obedience paradigm to the sole relationship between experimenter and participant. What is a multivocal reality in which people are torn between two voices invoking different obligations and placing incompatible demands on the participant (thereby creating the tension and the drama of the situation) is rendered univocal, as if the participant were in thrall to the sole voice of the experimenter and was unaffected by everything else. But, again, this cannot explain Milgram's own findings. When one looks closely at the points where people are most likely to disobey the experimenter, they are precisely the points where the learner makes his most powerful pleas – notably 150 V where (as we have described above) he first demands to be released from the study and, to a lesser degree, at 315 V where he declares that he is no longer part of the experiment (see Packer, 2008). The voice of the learner – as well as the experimenter – clearly does matter.

The deeper problem here is that, in this process of reduction, and by taking the influence of the experimenter for granted, all the important questions on which Milgram deliberates in his earlier notes – about which voice is listened to, about how the different conditions impact on this (and through what processes), and about how the experimenter (or the learner) achieves precedence – are instantly ruled out. These are questions of general relevance for psychology. For issues of social significance – say, how we should respond to immigrants – we do not come to an understanding through a process of silent contemplation. Rather we are assailed on all sides – in conversations with friends, headlines in newspapers, debates on the radio, television, and the internet – by various voices telling us what to think and do. The key question is how we allocate authority and credence among these voices. Psychological research, however, generally ignores this. Most of the time people are placed in a laboratory and asked to respond on their own. Occasionally, and at most, we look at how they respond to a single influence message. Milgram's paradigm is about the only one in which we are placed between several voices. It bears the promise of helping us understand the general nature of social understanding (and not only its toxic outcomes). The agentic state explanation kills that promise stone dead.

Forward to the Past: From 'Bureaucratic Sleepwalker' to 'Engaged Follower'

One obvious way to get beyond the impasse of the 'agentic state' explanation is to return to some of Milgram's earlier explanations. There are two elements in particular that can be drawn upon. First, Milgram points to the way in which the study is sold by the experimenter (and seen by the participant) as a worthy enterprise (Milgram, 1963, point 2 in the discussion). Second, he points to the way in which the participant comes to the study in order to form a relationship with the experimenter and hence this takes precedence over his relationship with the learner (point 3 in the discussion). In a later paper Milgram (1965) develops this last idea and talks about the way in which different experimental conditions (e.g., degree of spatial proximity) may impact on the formation of a group bond between the experimenter and participant, and hence affect the degree of obedience. This, then, begins to be a means of explaining the different levels of obedience in the different studies.

Putting the two elements together, one could argue that people are more likely to shock when they identify with a worthy scientific enterprise and with the experimenter as a representative of that enterprise. They are less likely to shock when they identify with victim as a fellow citizen. Put differently, one could characterize Milgram's compliant participants (like the Nazi bureaucrats) as 'engaged followers' who were far from unaware of the pain they were inflicting but who, ultimately, proceeded because they thought it was the right and noble thing to do.

There are a number of convergent pieces of evidence to support this approach. First, and most directly, using an

adapted version of the Milgram paradigm in which one is asked to commit increasingly difficult acts of derogation against members of other groups, participants proceed further when they are made to identify with science than when they are not (Birney et al., 2013).

Second, if one asks contemporary subjects to indicate how much they think they would identify with (1) the experimenter and (2) the learner in Milgram's different experimental variants (using the descriptions of these variants in his 1974 book), then there is a strong negative correlation between identification with the learner and the proportion of participants in the actual studies who went up to 450 V, a strong positive correlation between identification with the experimenter and the proportion of participants who went on to the endpoint, and an even stronger positive correlation between relative identification with the experimenter (i.e., identification with the experimenter minus identification with the learner) and this proportion (Reicher et al., 2012).

Third, when one examines the script used to introduce the study, Milgram devotes much time to explaining why the study is unique and important. That is, the participants do not come to the idea that they are involved in a noble enterprise of their own accord. Rather the experimenter actively construes the enterprise as noble in order to bind them in. Moreover, when the experiments were completed and Milgram wanted to reassure the participants, he uses almost identical language concerning the unique and important nature of the study (though this time the argument is that it provides new understandings of the obedience process rather than new understandings of the learning process). What is more, looking at participants reactions to this reassurance (which are contained in Box 44 of the Milgram archive) there is a clear relationship between belief in the scientific endeavor, on the one hand, and contentment with one's own participation, willingness to participate again, and willingness to persuade others to participate on the other (Haslam et al., 2013). Both during and after the study, then, what people did and how they felt was a function of the extent they could be signed up for the cause of science. This did not happen of itself. Compliance could not be taken for granted. Rather, Milgram and his experimenter succeeded in producing 'obedience' through their skills as recruiting sergeants for the cause.

Science, Ethics, and a Last Word

Any mention of how participants felt, and how Milgram reassured them, necessarily takes us to the issue of ethics. This is something that no discussion of the obedience research can or should ignore – for the studies are as famous (or rather notorious) for the cost to participants as they are for the gain to science. In general the two issues are treated separately leading to two camps, the one which condemns Milgram for his ethical misdemeanors, the other which praises him for his scientific contributions.

The ethical controversy was sparked immediately after Milgram's first publication in 1963 when Baumrind (1964) published a coruscating commentary in which she accused him of manipulating, embarrassing, and discomforting his participants while showing no concern for their suffering. She further dismissed his suggestions that any tensions were dissipated before people left the laboratory. But even this was mild compared to some other comments. The renowned child psychologist and concentration camp survivor, Bruno Bettelheim, declared the studies to be "vile" and "in line with the human experiments of the Nazis" (cited in Blass, 2004, p. 123). A newspaper editorial described them as "open eyed torture" (cited in Blass, 2004, p. 121).

Milgram confronted these criticisms head on. He collected systematic data after the experiment about the experience and reactions of participants. These largely bear out his contention that, whatever stresses were apparent during the studies, there is little evidence of distress after the studies. So, for instance, nearly 85% of participants were glad or very glad to have taken part and only just over 1% were sorry or very sorry. Similarly, only 7% of participants said that they had been bothered quite a bit by their experience. Overall, Milgram contends that most people were positive about the study and felt that it was time 'well-spent' (Milgram, 1974, p. 198).

One could obviously respond by arguing that even 7% of people feeling bothered, or 1% of people feeling sorry with what they had been led to do is unacceptable. But perhaps this misses the larger point. The controversy between Milgram, Baumrind, and others proceeds on the assumption that any problems have to do with whether participants were distressed – so if they were not distressed, there is no problem. But is there really no problem if there was no distress? Should not people have been distressed? Should not they worry about having apparently delivered lethal shocks to an innocent victim, and should not we worry that they are prepared to persuade others to participate in such studies in the future? That is, Milgram may have reassured his participants but at the cost of getting people to believe that it is fine to suffer for science, and fine to make others suffer for science. Arguably, this is the real ethical issue with the obedience studies, but it is one that has been almost totally overlooked. We are rightly concerned with whether individuals suffer in our studies, but, there is potentially a problem if this comes at the expense of consolidating ideologies which facilitate collective suffering in society.

To conclude, then, Milgram's obedience studies undoubtedly reveal, as he intended, a phenomenon of great consequence. However it is arguable that, when it comes to understanding this phenomenon, we have been led up a blind alley – or rather two blind alleys, one scientific and one ethical. On the scientific side, Milgram's agentic state account leads us away from asking how people are led to engage with a toxic cause and how authorities advance such causes. On the ethical side, the 'individual harm' debate leads us away from asking about the dangers of advancing causes that reconcile people to collective harm-doing.

From this perspective the scientific and ethical dimensions of the obedience studies are not two separate issues, but two sides of the same coin. Progress depends upon bringing them back together. It is precisely by understanding how people can be led to identify with the powerful and justify harm-doing against the powerless that we can disrupt the ease with which people abuse or else are complicit with abuse. This could be more uncomfortable than we imagine, for it may come very close to home. Indeed, we now look in horror at the past use of

racial supremacism as a justification for excluding and even exterminating the racial other. What we may be less aware of, and what Milgram's studies point to, is the continuing power of an ideology of scientific progress as a means of getting people to inflict harm and yet still feel noble.

Abstract

Obedience is the act of carrying out the requests or commands of a person of higher status within a social hierarchy. The most distinctive feature of the social-psychological approach to obedience is the primary role it accords to situational determinants. The foremost social-psychological contribution to understanding obedience was that of Stanley Milgram, whose experiments demonstrated that a surprisingly high proportion of normal people would obey orders to hurt an innocent person. Milgram saw his experimenter as representing a legitimate authority – a person who is deemed to have the right to issue orders to others who, in turn, feel obligated to obey them. According to French and Raven, the power of authorities or other agents of influence can derive from five additional sources besides their legitimacy. These are: reward, coercive, expert, referent, and informational power. Kelman has pointed to three processes that help overcome the normal human reluctance to hurt another person: authorization, routinization, and dehumanization. Kelman and Hamilton distinguish among three broad individual orientations toward political authority: rule-oriented, role-oriented, and value-oriented. A current research emphasis is the study of harmful obedience in the workplace. Available evidence suggests that obedience to authority is one of the universals of social behavior, transcending both time and place.

Obedience refers to the act of carrying out requests or commands emanating from a person of higher status within a social hierarchy. It is to be distinguished from compliance – which also refers to a form of acquiescence, but does not necessarily involve a situation of status inequality. Obedience is also different from conformity (*see* Conformity: Sociological Aspects). In the latter, the source of influence comes from others of equal status to the target of influence; such as, a group of peers or other members of one's society or culture (*see* Social Influence, Sociology of). Additionally, while obedience – as well as compliance – is a result of direct influence attempts, conformity is usually the product of implicit, indirect group pressures felt by the individual to be impinging on him or her. Thus, while obedience represents the maintenance or creation of social inequality, conformity is a social leveler.

Distinctive Feature of the Social-Psychological Approach

Social-psychological perspectives on obedience to authority see it as a necessary feature of organized social life, contributing importantly to its efficient and orderly functioning. Their most distinctive feature is the primary role accorded to situational factors. Grounded in Kurt Lewin's ahistorical approach, which emphasized contemporaneous determinants of behavior, social psychologists tend to focus on situ- ational determinants to account for variations in obedience. This is in contrast to the personality psychologist who focuses on inner, stable dispositions to account for obedience and its variations. A prime example of the latter is the personality construct of authoritarianism, which consists of a number of interrelated elements, including a powerful propensity to obey authority (Adorno et al. 1950, Altemeyer 1988).

The Contribution of Stanley Milgram

The most important social-psychological contribution to understanding obedience was that of Milgram (1963, 1974). Although his aim was to study destructive obedience, his findings and insights are readily applicable to more mundane and benign forms of obedience. Milgram conducted a series of laboratory experiments at Yale University from July 1961 to May 1962 to answer the following question: If one person orders another to harm a third person, under what conditions would the second obey the first person's orders and under what conditions would he or she defy them? In his experiments, subjects who had been recruited for a study of memory and learning were instructed to give what appeared to be increasingly dangerous shocks to a learner every time he made a mistake on a word-matching task. The subjects delivered the shocks by pressing one of 30 switches arranged horizontally along the front panel of a box-shaped 'shock-generator.' Each subsequent switch was labeled with higher and higher voltages of shock, in 15-volt steps, beginning with 15 volts for the first switch and ending with 450 volts for the last one. The rule was that the subject teacher had to increase the shock level one switch at a time each time the learner made an error. In some of the conditions, as shock levels became more intense and painful, the learner responded with shrieks and complaints of increasing urgency and demanded that the experimenter terminate the experiment. After a certain point, the learner became silent, suggesting the possibility that he may have passed out.

The main finding was an unexpectedly high degree of obedience. As many as 65 percent of the subjects, ordinary residents of New Haven and Bridgeport, Connecticut, were fully obedient, that is, continued administering what they were led to believe were increasingly painful and dangerous shocks until the 450-volt maximum in response to the experimental authority's orders. In actuality, the shocks were not real and the learner was

a confederate who made errors according to a pre-arranged schedule. Some of Milgram's additional findings were: Obedience declined as the distance between teacher and learner was reduced and when the distance between the experimenter and subject was increased; obedience increased when the subject was only indirectly involved in punishing the learner, that is, he read the wordlist, but someone else pressed the switch; the subject's obedience rate diminished drastically after seeing two of his peers refuse to continue and thereby providing models of disobedience; and men and women were equally obedient, although the latter reported experiencing greater tension. Milgram believed that such extreme obedience to potentially destructive commands is made possible by the acceptance of the authority's definition of the situation and by the subject's entry into an 'agentic state,' a mental state whose central feature is the relinquishing of responsibility to the person in charge. According to Milgram, his experimenter represented a legitimate authority, a person who is seen as having the right to issue orders and as someone whom we feel an obligation to obey.

If the legitimacy of an authority is seen to be of prime importance in enabling him or her to be a powerful source of influence, a logical question is: How do authorities create and maintain their legitimacy? Recent research by Tyler (1997) has addressed this question. He distinguishes between two approaches that suggest why people see authorities as legitimate, and, hence, feel an obligation to obey them: an instrumental model and a relational model. According to the first approach, a prime determinant of peoples' acceptance of the legitimacy of a leader is whether they are seen as a source of benefits or desirable outcomes. According to the second approach, it is the nature of the treatment people receive from authorities – in particular the integrity and caring that mark their actions – that will determine their perceived legitimacy. Tyler finds that, although both instrumental and relational factors have an influence, the latter is the more dominant factor in judgments of an authority's legitimacy.

Other Social-Psychological Approaches

According to French and Raven (1959) and Raven (1999), a person's authority or power to influence others can derive from other factors besides from his or her legitimacy. Specifically, according to these authors, social power can derive from six different bases. Besides legitimate power, they are: reward, coercive, expert, referent, and informational power. When an authority or persuader has reward power, people obey or yield because they see the former as a potential source of rewards. Coercive power is operating when people yield out of fear of punishment. Persons are said to possess expert power when others go along with their wishes because of their expertise or special knowledge. An authority or influencer is said to have referent power when people acquiesce to his or her commands or wishes because they like or identify with him or her. And finally, an authority or other source is wielding informational power when people obey or are influenced because they find the information provided by that person to be intrinsically convincing or compelling.

According to Kelman (1973), there are three social processes that help weaken the normal human reticence against inflicting harm on another and thereby facilitate people's obedience to destructive orders: authorization, routinization, and dehumanization.

Through authorization, individuals are relieved of the necessity of assessing the morality of the actions they are directed to carry out. When an action is authorized, the usual moral considerations fade into the background, and the individual no longer feels responsible for his or her actions, nor any guilt, should those actions be harmful. Routinization – the absorption of the individual in the mechanical and routine details that are necessary for carrying out the authorized actions – minimizes the possibility that he will worry about its consequences. Dehumanization – viewing the target of one's harmful actions as less than human – further insures that the morality of the commands issued by an authority will not be questioned.

Going beyond obedience in authority–subordinate relationships between individuals, Kelman and Hamilton (1989) analyzed the effects of political authority – the nation–state and its various institutions – on the individual citizen. A central feature of their analysis is a threefold distinction among people's broad orientations to political authority – rule, role, and value orientations – that they see as potential mediators of the nature of citizens' responses to morally questionable policies or destructive orders, as the following quote indicates:

> For the *rule-oriented*, moral principles are largely irrelevant both to the actions of the citizen in an authority context and to the actions of the state in pursuit of its primary purposes: ensuring public order and national security. This view has a cynical overtone. The state cannot afford the luxury of concerning itself with higher principles, and individuals can be expected to do only what they must in order to stay out of trouble. For the *role-oriented*, special moral principles apply to the citizen in relation to the state as well as to the state itself. The morality of obedience—the obligation to obey and support the government—at the level of the individual citizen and the duty to pursue the national interest at the level of the state both override standard moral considerations. Finally, for the *value oriented*, principles of personal morality continue to govern the behavior of individuals as citizens, and adherence to moral principles is fundamental to the legitimacy of state action. Actions by and on behalf of the state may not always conform precisely to the expectations that govern personal relations, but they have to be chosen and evaluated with reference to standard moral principles (Kelman and Hamilton 1989, italics added).

A Contemporary Problem: Harmful Obedience in the Workplace

An important implication that Milgram (1974) had drawn from his research was about the potential dangers inherent in organizational behavior: When an individual 'merges... into an organizational structure, a new creature replaces autonomous man, unhindered by the limitations of individual morality, freed of humane inhibition, mindful only of the sanctions of authority.' This observation about the evaporation of individual responsibility in hierarchical organizations anticipated the kinds of tragedies that later resulted from car manufacturers' employees' readiness to

carry out their bosses' directives to produce unsafe automobiles, and the tobacco companies' employees' acquiescence to policies aimed at deceiving the public.

A current emphasis in research on obedience to authority is the systematic study of this 'darker side' to behavior within hierarchical organizations such as businesses and companies. Thus, for example, Hamilton and Sanders (1995), in a cross-cultural study, examined the factors that would affect judgments about a subordinate's responsibility when his company's actions could result in physical harm to the public. Brief et al. (2000) showed that, when a company president's orders not to hire minority group members was accompanied by a business justification – 'Our organization attempts to match the characteristics of our representatives with the characteristics of the population to which they will be assigned' – subordinates were more likely to discriminate against Black job candidates than when no such justification was provided.

The Pervasiveness of Obedience to Authority

Obedience to authority would seem to be one of the universals of social behavior, transcending both time and place, as suggested by two quantitative analyses. One analysis, using the findings of Milgram's standard conditions and those of all the replications conducted by others, correlated the amount of obedience found in each study with its year of publication and found absolutely no relationship between the two variables (Blass 2000). Another analysis (Blass 1998), also involving Milgram's standard conditions and their replications, reveals that the average obedience rate found in US studies (61 percent) was very similar to the average rate of obedience obtained in replications carried out in other countries (66 percent). As Milgram once wrote:

> We do not observe compliance to authority merely because it is a transient cultural or historical phenomenon, but because it flows from the logical necessities of social organization. If we are to have social life in any organized form—that is to say if we are to have society—then we must have members of society amenable to organizational imperatives (letter to Professor Alan Elms, Sept 25, 1973; The Stanley Milgram Papers, Yale University Archives).

Future Directions

Recently, there has been a discernible shift in emphasis away from obedience toward defiance – both as a focus of research (e.g., Modigliani and Rochat 1995, Rochat and Modigliani 2000) and in the implementation of changes in the workplace that facilitate employees' disobedience of illegitimate or destructive orders from their superiors, such as the creation of hot lines and the placement of ombudsmen. In the future, one can expect a substantive increase in these kinds of developments.

Obesity and Labor Market Performance

Susan L Averett, Lafayette College, Easton, PA, USA

Abstract

Obesity is the most pressing public health problem in developed countries and is rapidly becoming so in developing countries. Obesity is associated with a host of comorbidities and strains health care systems around the globe. Obesity is also associated with poor labor market outcomes such as lower wages and a lower probability of employment. While this negative correlation between obesity and wages/employment is well documented across numerous countries, sorting out causality from correlation has been challenging. Most studies that credibly disentangle correlation from causation find a negative and significant causal effect of obesity on wages and employment, particularly for women.

Introduction

We live in an increasingly obesogenic environment. A progressively more sedentary lifestyle coupled with low-cost, highly palatable calorically dense food has led to rising rates of obesity. Obesity is rapidly becoming the most urgent public health problem in the world. Obesity rates have been on the rise worldwide and even developing countries have not been spared the obesity epidemic. In fact, in many developing countries, the proportion of the population that is overweight or obese exceeds that which is underweight (Mendez et al., 2005). Recent estimates from the World Health Organization (WHO) indicate that 65% of the world's population lives in countries where overweight and obesity kill more people than does underweight and worldwide obesity rates have nearly doubled since 1980 (WHO, 2013).

Obesity is well known as a risk factor for a considerable number of diseases and medical conditions. These include diabetes, heart disease, stroke, hypertension, arthritis, sleep apnea, some cancers, and asthma. These conditions are responsible for a large and growing portion of medical care costs. Currently, obesity rivals, and according to some estimates surpasses, smoking as the leading preventable cause of death worldwide (Hennekens and Andreotti, 2013).

In addition to its negative impact on health and medical expenditures, there is a growing evidence that the obese, particularly women, pay a penalty in the labor market in that they are less likely to be employed and when employed they have lower wages (e.g., Averett, 2011, 2014; Averett et al., 2013). In this article, I first discuss the reasons why the obese may have lower wages and/or a lower probability of employment. I then outline the strategies and findings of the empirical studies that have attempted to determine if obesity is the cause of adverse labor market outcomes.

Obesity and Labor Market Outcomes: What Is the Relationship?

In the mid-1990s, economists and other social scientists began to explore the possibility of a causal relationship between obesity and labor market outcomes whereby they hypothesized that obesity might be the cause of lower wages and poor employment prospects (e.g., Averett and Korenman, 1996). Since that time, this literature has grown in both volume and sophistication of method.

Establishing a clear causal connection between obesity and labor market outcomes is not as straightforward as it might initially appear. Clearly, the aforementioned health conditions that the obese may suffer as a result of their obesity may limit their productivity in the labor market or may directly limit the type of work they can do and this may be a primary cause of lower wages for the obese. This may be particularly true for the morbidly obese and less of a concern for those whose obesity is not as severe. It likely also depends on the occupation – one can imagine that the obese are more incapacitated in occupations that require more physical exertion or agility but less impaired in an office setting, which is more sedentary. In addition, in some occupations cultural norms dictate that a thin person is appropriate for the job – fashion modeling is an oft cited example. In fact, in a column for Business Week magazine in 1998, Nobel Prize winning economist Robert Barro argued that an employee's physical appearance is a legitimate job qualification to the extent that it is valued by customers and coworkers. While he was speaking of beauty, in modern society beauty and obesity tend to be inversely correlated.

Obesity has also been directly linked to absenteeism. Given the health problems faced by the obese, they are more likely to be absent from work. Using US data, Cawley et al. (2007) reported that obese women were 61% more likely to miss work than were their nonobese counterparts independent of their occupation. Results for men were mixed and varied by occupation. He estimated the annual costs of obesity-related job absenteeism in the United States to be as high as 4.3 billion dollars in 2004. Using data from Europe, de Galdeano, 2007 confirms that for women, the costs of absenteeism associated with obesity are statistically significant, although for men obesity was not correlated with higher absenteeism.

Obesity may also negatively affect the acquisition of what economists call human capital – the skills that one brings to the work place that make them productive and hence enhance their employability and wages. Obesity could potentially affect educational attainment through several channels. The most obvious is a poor diet that fails to provide adequate nourishment. This idea that the obese are misnourished is gaining traction in the development economics literature where there is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.94039-X

discussion of a 'nutrition transition' whereby poorer countries adopt the dietary habits of more affluent countries and thereby also the obesity problem of more affluent countries. Yet, this misnourishment has also been noted as a problem in more developed countries including the United States. A lack of important micronutrients may impair the academic performance and/or brain development of children directly reducing their human capital achievement.

Another way that obesity may reduce human capital acquisition is that teachers may discriminate against obese students making it difficult for obese children to perform well because they may feel stigmatized and even if they perform well, they may face discrimination in grading by teachers. There is a growing body of empirical evidence using data from the United States and Europe that indicates that obese children and adolescents have lower academic outcomes thus limiting their future productivity although this finding is not universal across all studies and more research is necessary on this topic (see Scholder et al., 2012, for further discussion). There is also growing support that the medical consequences of obesity may operate to cause physiologic brain changes that could impair general cognitive function or performance in some cognitive areas leading to lower educational attainment. All of the above suggests that obesity itself may be a cause of lower human capital attainment, which would translate into lower wages in the labor market.

Labor market discrimination is another possible explanation for the link between obesity and wages or employment. In this case, it is not that the obese are less productive than the nonobese but rather that they face discrimination in the labor market. Such discrimination could come directly from employers who have a subjective dislike of obese persons and thus do not want to hire them or if they hire them, they do so only if they are less expensive than nonobese employees. This 'taste-based' theory of discrimination was put forth by Nobel prize winning economist Gary Becker (1957) who theorized that this type of discrimination emanating from employers was not sustainable in the long run due to competitive pressures because employers who were unwilling to hire the obese would have higher costs and hence go out of business. It is also possible that customers may be less willing to purchase goods and services from the obese. That customers might have a subjective distaste toward the obese is consistent with the considerable evidence that the obese are stigmatized. In the United States there is evidence that discrimination against the obese is as prevalent as racial or gender discrimination.

Another source of labor market discrimination against the obese may be statistical discrimination. In contrast to taste-based discrimination, this is not based on any subjective dislike of the obese but rather refers to a situation where employers do not have perfect information about potential employees. This leads employers to make hiring decisions about individuals based on the characteristics of the group to which they belong. If employers believe obesity is associated with a lack of self-discipline and professionalism then they may choose a nonobese person to hire even if the obese person they are interviewing is highly productive.

Finally, the obese might earn lower wages because of their relatively greater health care costs. This is particularly salient in the United States where employers are responsible for a considerable portion of their employees' health care costs. Employers can compensate workers with a combination of wages and benefits. Economic theory posits that under certain conditions, employees pay for their own benefits in terms of higher wages. The employer is generally indifferent as to the exact wage/benefit combination as long as profits remain the same. Since the obese are likely to incur higher health care costs, their employer may pay higher premiums for employer-sponsored health insurance and therefore compensate the obese with lower wages to maintain the same cost of the wages/benefit mix (Bhattacharya and Bundorf, 2009).

All of the above explanations point to obesity as being a *cause* of lower wages. However, the causality may run the other direction such that those with lower wages become obese in part because they cannot afford healthy food and thus rely on calorie-dense fast foods. In most developed countries, there is an income–obesity gradient such that those with lower incomes are more likely to be obese (e.g., Averett, 2012; García Villar and Quintana-Domeque, 2009). It is also possible that an adverse labor market outcome leads to depression and/or low self-esteem and that this subsequent depression or low self-esteem leads to weight gain. Conversely, the obese, particularly women, may believe their marriage market prospects are low, and hence may invest more heavily in labor market–oriented human capital and actually have higher wages as a result of their obesity. The potential for reverse causality may be particularly relevant when employment is the outcome because obesity can be the cause of substantial work disabilities as noted earlier.

In contrast to the above explanations, it may be that there is no causal relationship in either direction between obesity and wages but that a third factor creates a correlation between obesity and labor market outcomes. For example, obesity could be correlated with undesirable personality traits that affect the productivity of the obese and hence their wages and their ability to find employment. In this case, the negative correlation between obesity and wages is not causal. These personality traits might include laziness, inability to delay gratification, lack of self-control, or poor social skills – all traits that the general public has often associated with obesity.

Another unobserved variable that might link obesity to poor labor market outcomes is that the obese may have a higher subjective discount rate; i.e., a higher degree of impatience, which implies a stronger preference for present consumption relative to future consumption. Thus, they may overeat today without thinking about the consequences that occur in the future. There is evidence that the marginal rate of time preference has increased leading to the obesity epidemic because individuals increasingly discount the future more heavily (Komlos et al., 2004). In addition, some people have high-discount rates for very short horizons but have considerably lower discount rates for longer horizons, thus indicating that some people are less patient in immediate future choices than in distant future choices. When people behave this way, economists say that their preferences are time-inconsistent. There is evidence that persons with a stronger tendency toward time-inconsistent preferences have higher BMIs (Ikeda et al., 2010).

These unobserved traits (e.g., laziness, high-discount rates, or time-inconsistent preferences) may make some individuals

both more likely to overeat and to invest less in wage-enhancing human capital leading to a negative correlation between wages and obesity. In other words, it may be this third factor that is the cause of their poor labor market outcomes; not their obesity directly. If this is the case then obesity and labor market outcomes would have what economists call a spurious correlation.

Obesity and Labor Market Outcomes: Empirical Methods and Findings

The fact that obesity is a growing concern around the world generating poor health and high costs associated with treating its comorbidities has led researchers to attempt to determine if obesity is the *cause* of adverse labor market outcomes. A major challenge in this line of research has been sorting out causation from correlation. Scholars have made use of complex econometric methods to identify there is any causal relationship at all between obesity and wages/employment.

Ideally, to measure the effect of obesity on labor market outcomes one would conduct a randomized controlled trial in which obesity was randomly assigned by the investigator and subsequent labor market outcomes were observed. Such an experiment would, of course, be unethical so the bulk of the research in this area relies on observational data collected through surveys. Most research in this area relies on the BMI as the measure of adiposity because it is easily calculated from height and weight. The BMI is calculated as weight (kg)/height^2 (meters). According to the WHO's international standards, a BMI of 25 or more signals overweight, and a BMI of 30 or more indicates obesity.

Early research linking obesity to labor market outcomes used ordinary least squares (OLS) regression – a statistical method that allows researchers to relate the outcome of interest (e.g., wages) to obesity while controlling for the influence of other factors that predict wages including education and work experience in order to isolate the effect of obesity on wages. The vast majority of these studies find a negative relationship between obesity and the labor market outcome of interest, particularly but not exclusively for women. Yet, although these models generally control for a host of observable socioeconomic and demographic factors, OLS cannot address the potential for reversed causality nor can it rule out that a third factor, unobserved to the researcher, is the cause of both the obesity and the labor market outcome. Thus, studies relying on OLS regression can only be taken as suggestive of a causal effect.

Given the limitations of OLS, researchers have used a variety of more sophisticated econometric techniques to determine if there is a causal effect of obesity on labor market outcomes. In what follows, I provide a brief description of these methods and the findings of the studies that employ them. Readers interested in a more technical discussion of each of the methods described below should consult Averett, 2011.

Many researchers relate an early measure of obesity to a later labor market outcome arguing that this temporal ordering of events cannot reflect reverse causality. Studies using this method report a negative association between obesity and wages, particularly for women. Results from these studies are most convincing if this early measure of BMI is taken prior to the labor market entrance of the individual so that it is not possible for the BMI to be affected by the labor market outcome.

Comparing siblings, one who is obese and the other who is not, has also been used to examine the relationship between obesity and wages on the assumption that differences between siblings removes the variation in weight attributable to a shared family environment. However, even after differencing across siblings there remains variation in weight ascribed to genetic makeup unshared by siblings and the variation in weight attributable to nongenetic factors. To the extent that these factors are not captured by the observable factors controlled for in the model such as education, or if parents treat children in the same family differently as a response to early academic potential that is related to future wages, this method will yield biased estimates of the effect of obesity on wages. Other researchers have used monozygotic twins as another way to remove unobservable genetic factors correlated with obesity. In this case, the researcher can control completely for genetic propensity to be obese since monozygotic twins share 100% of their genes, however, sample sizes of monozygotic twins tend to be small and thus the results of these studies may have limited external validity.

Longitudinal data (i.e., data where the same individual is followed over time) can be particularly useful because they enable the researcher to control for unobservable or hard to measure factors that might affect both obesity and the labor market outcome of interest as long as these unobservable factors are constant over time. As noted earlier, unobservable characteristics that might influence obesity and labor market outcomes could include an individual's rate of time preference, or a personality trait such as laziness. Essentially, with this type of data, each individual serves as their own control. However, if these unobservable factors affecting both weight and wages are time-varying they will not be accounted for with this method.

If the concern is that there is reversed causality or that there are important unobservable factors that vary over time then the method of instrumental variables (IV) is preferred. The drawback of this technique is that this technique involves finding a variable (the instrument) that is highly predictive of an individual's obesity but completely unrelated to that same individual's labor market outcomes except through its effect on obesity. As noted earlier, there are many potential factors that are related to both the probability that someone is obese and their labor market outcomes. Thus, finding plausible instruments is challenging.

Given that roughly half the variation in weight across individuals is genetic in origin; many studies have used the weight of a biological relative as an instrument. Yet, the validity of this instrument is questionable if both the respondent and the biological relative are affected by a common household environment that is also directly correlated with their labor market outcomes. In other words, it is possible that a substantial part of the genes responsible for obesity are also responsible for other factors that affect labor market outcomes, such as willingness to delay gratification (time discount rate) or other unobserved characteristics. Cawley (2004) argues for the validity of this instrument citing studies that have been unable to detect any effect of common household environment on body weight. Economists have also begun to use an individual's own genetic information as IV. Such information on specific genes

linked to obesity should be a strong instrument for obesity and is likely to be used more in the future, if it is available in the data.

Other instruments that have been used include the presence of other obese persons in the household, being an oldest child, and whether or not a parent has been prescribed medication for obesity. These are less likely to be valid instruments in that they are also likely correlated with an individual's labor market outcome independent of their association with obesity. In addition, a few studies have used the average BMI and the proportion obese who live in the same geographic area as the individual as an instruments. However, given that location of residence is a choice, this instrument could be related to occupational choices or other labor market characteristics rendering them invalid.

Using the methods described above, numerous studies based on US data have assessed the relationship between wages and obesity or wages and employment. One of the most robust findings from this research is that obese white women generally earn less than their nonobese counterparts even after using a wide array of statistical techniques as described above. That the effect is mainly found for women may indicate a form of cosmetic discrimination, which may exist in a culture that correlates thinness with attractiveness for women.

In addition to the United States, scholars around the world have conducted a number of studies relating obesity to labor market outcomes using data from Australia, China, Denmark, Finland, France, Germany, Iceland, Sweden, Taiwan, and the U.K. Similar to the case with US data, a negative and statistically significant effect of obesity on wages and employment is often, but not always found, particularly for women even using IV or other methods.

Even studies using data comparing several European countries have found that there is an obesity penalty in the labor market (e.g., García Villar and Quintana-Domeque, 2009). Assessing if the obese earn lower wages in Europe is particularly challenging because European labor markets are generally characterized by more compact wage distributions, a considerable share of the labor force in the public sector, and more rigid wage structures, which leaves little room for employer discretion with respect to wages.

The size of the effect found in this literature is economically meaningful. For example, the results in Cawley (2004) indicate that a difference in weight of 2 standard deviations among white females is associated with a difference in wages of 9%. This is equivalent to 1.5 years of education or 3 years of work experience.

The vast majority of the research in this area uses the BMI cutoff of 30 or over as the measure of obesity. But, cultural norms regarding social acceptable body size may play a role in whether or not there is a labor market penalty associated with obesity. In some cultures, thinness may be prized more than in others. Thus, perhaps the best measure is a relative measure of obesity – how much an individual's weight differs from the social norm may determine if they face lower wages. There is some empirical evidence for the relative threshold but more work remains to be done on this question. Other studies have noted that women's wages are highest at a body weight well below the BMI of 30 indicating a 'premium for thinness' that indicates that looks, rather than poor health, is driving the obesity penalty that we observe for women.

It is possible that cultural norms for thin body types are inversely related to the obesity prevalence in a society. If this is the case, in societies with relatively high obesity rates, the obese should have a lower wage penalty. Conversely, in countries which place a premium on frequent social interactions we should expect to observe a higher labor market penalty for obese persons; i.e., the obese will earn lower wages. There is some evidence in support of this hypothesis, particularly for women (e.g., García Villar and Quintana-Domeque, 2007).

The studies discussed above have all relied on BMI as the measure of whether an individual is obese or not. This is not surprising as social science data sets that contain detailed labor market outcomes were often not intended to collect health information and so it is fortunate that some collected information on height and weight. It has been established that BMI itself is not an accurate measure of obesity, particularly for males because it does not distinguish fat from muscle (Burkhauser and Cawley, 2008). In addition, in most data sets height and weight are self-reported and thus may be systematically misreported. Burkhauser and Cawley note that the "social science research on obesity would be enriched by greater consideration of more accurate measures of fatness" (Burkhauser and Cawley, 2008: p. 520).

Given the limitations of the BMI as a measure of adiposity, some studies have used fat-free mass (FFM) and body fat (BF) to examine the link between obesity and wages (e.g., Wada and Tekin, 2010). Similar to the studies using BMI, these studies often find that those who have higher BF and lower FFM to have lower wages. One study found that no association of BMI with wages or employment for men but did find that FFM and waist circumference were predictive of wages and employment. For women, all three measures were predictive of lower wages and a lower probability of employment (Johansson et al., 2009). This evidence is consistent with the concern that BMI is not an accurate measure of fatness for men and heightens awareness of the need for more data sets that include these more accurate measures of adiposity.

Another measure of obesity that is sometimes available is waist circumference. Waist circumference is a measure of central obesity, which occurs when excess fat is centrally distributed and some argue that it has at least two advantages over BMI. First of all, it is a stronger predictor of morbidity and mortality and second, it is a visible measure of fatness, which might be interpreted by employers, customers, or coworkers as an unattractive physical attribute. Some studies that have used waist circumference to measure obesity have also found evidence that the obese earn lower wages.

As noted earlier, the 'gold standard' for ascertaining causality is the randomized experiment. While such a study is ethically not feasible here, a related type of study is an audit study. In an audit study, fictitious individuals who are identical, except for some outwardly observable characteristic, apply for jobs and any group differences in outcomes are interpreted as reflecting discrimination. Rooth (2009) sent two equivalent applications to advertised job openings with the only difference being that one had a picture of a person who was not obese while the other had a picture of that same person, which had been digitally modified to make the same person appear obese. The advantage of this approach is that it helps ensure that other productivity-related characteristics of the job applicant are held constant – after all it is the same applicant just with a different picture. In order to isolate the effect of obesity and not confound it with a poor

job interview, the outcome in this study was the call-back rate (offer for an interview) rather than an actual job offer or wages. The results from this study indicated that the obese were less likely to be called back for an interview than the nonobese, although there were some differences in call-back rates across occupations and gender.

The variation by occupation in call-back rates across the obese and the nonobese found by Rooth (2009) could plausibly be interpreted as evidence of customer discrimination. If employer discrimination were responsible for these differences, we would not expect them to exist across occupations. If customer discrimination is the cause of the lower wages among the obese, then we would expect the effect to be stronger in occupations that involve significant customer contact. This hypothesis is bolstered by the findings of other researchers who have reported that the negative relationship between the BMI and wages is larger in occupations requiring interpersonal skills and that it is often obese women in sales and service occupations who suffer the greatest wage penalties.

As noted earlier, the Becker model states that discrimination should be incompatible with profit maximization. As a simple, though indirect test of this theory, Brunello et al., 2009, used data from nine European countries to calculate the correlation between wages and obesity rates, which they found to be negative in each country. They then compared this correlation to an OECD-created measure of product market regulation (as a proxy for the degree of competition in the economy) and found that the negative penalty for obesity is indeed higher in those countries where there is less competition as would be predicted by the theory of employer discrimination. In contrast, Lundborg et al. (2010) using a large sample of Swedish men, concluded that the 18% lower wages of obese men compared to nonobese men were more likely due to statistical discrimination as it appeared in their data that employers used obesity as a proxy for physical fitness since in their data, the obesity penalty could be explained almost entirely by differences in cognitive skills, noncognitive skills, and physical fitness.

There is a strong, negative correlation between obesity and employment and wages, particularly for women. Moreover, a host of careful econometric studies using data from many countries suggests that obesity is likely the *cause* of these adverse economic outcomes. The available evidence suggests that discrimination plays at least some role in these adverse outcomes although more research on this is necessary. While a discussion of policy alternatives is beyond the scope of this article (interested readers can consult Averett, 2014, for a discussion of policy alternatives), this social disparity across the obese and the nonobese has captured the attention of policy makers around the globe who have increasingly stepped up efforts to tackle the causes of obesity. The research summarized here makes it clear that in addition to improving people's health, reducing obesity will likely also improve the economic well-being of the obese.

Obesity and Mortality

Neil K Mehta, Rollins School of Public Health, Emory University, Atlanta, GA, USA

Abstract

Obesity is now considered to be a major contributor to premature mortality globally. Despite great interest in this topic, there remains much uncertainty over the most appropriate methods that should be applied to obtain accurate estimates of the obesity–mortality association. This article reviews the current evidence on the obesity–mortality association. I discuss pertinent methodological issues and recent advances in our understanding of this association. I then discuss the obesity–mortality association in an international context and potential secular changes in this association.

Introduction

Population scientists are often interested in how behavioral factors shape the risk of dying. One such behavioral factor that is receiving much attention is obesity. While the causes of obesity include both behavioral and nonbehavioral determinants, there is a general consensus that the rising level of obesity globally is a result of shifting patterns of diet and physical activity. Obesity is now often considered to be a major contributor of premature mortality in high-income countries and is of increasing concern in low- and middle-income countries.

The purpose of this article is to review our current understanding of the magnitude of the association between obesity and mortality. Despite the great interest in the mortality consequences of obesity, there remains much uncertainty in the most appropriate methods that should be applied to estimate this association. Estimates of the number of deaths attributable to obesity and obesity's influence on life expectancy, both of which are of primary interest to population scientists, nearly always rely on estimates of relative risks derived from survey data linked to prospective death records. This stands in contrast to approaches used to estimate cigarette smoking's effect on these aggregate mortality indicators. For cigarette smoking, researchers have developed indirect techniques to estimate the fraction of deaths attributable to this risk factor. These indirect techniques use deaths from lung cancer as an indicator of the overall mortality consequences of smoking (Peto et al., 1992; Preston et al., 2010). To date, no analogous indirect techniques have been developed for obesity. Therefore, much of our understanding of the aggregate mortality consequences of obesity is based on estimates of relative risks for obesity derived from survey data. I focus this article on the various methods used to estimate these relative risks and how the choice of methods influences our understanding of the aggregate mortality consequences of obesity.

The organization of this article is as follows. I begin with a brief overview of some salient methodological concerns in estimating the obesity–mortality association. I next turn to a review of recent evidence on the role of 'obesity histories' in helping to better characterize this association. I then discuss the obesity–mortality association in an international context and potential secular changes in the obesity–mortality association, respectively. I limit the discussion primarily to studies that use body mass index (BMI) as it is the most widely available indicator of weight status in survey data. In national populations, the correlation between BMI and other weight status indicators such as waist circumference and waist-to-hip ratio is generally high (Flegal et al., 2009; Vazquez et al., 2007). Current guidelines define obesity as a BMI ≥ 30.0 kg m^{-2} and overweight as a BMI of 25.0–29.9. In this article, I use the term 'obesity' in a general sense to refer to a BMI that is higher than optimal.

Methodological Concerns

Causal Identification

Because estimates of relative risk for obesity are based on observational studies, unobserved selection into the obese category is an important threat to causal identification. However, unlike other 'exposures' commonly examined in the social sciences, evidence supporting the causal effect of obesity on mortality can also be found in results from experiments conducted across species and from human clinical studies. Two large studies of bariatric surgery indicate that those who underwent surgery experienced 20–40% lower mortality compared to 'control' groups over a 7–15 year period (Adams et al., 2007; Sjöström et al., 2007). Neither study, however, was based on a random allocation of subjects into treatment/control groups nor was conclusive in isolating weight loss versus other factors as the direct cause of the mortality reduction. Experimental studies in nonhumans indicate that caloric restriction is associated with large reductions in mortality (Colman et al., 2009; Weindruch and Sohal, 1997; Weindruch and Walford, 1988). Vasselli et al. (2005), for example, show that obese rodents who were randomized to a weight loss diet experienced a 45% lower mortality compared to rats that remained on an obesity-sustaining diet over a 3 year period.

Instrumental variable approaches have also provided insights into the causal effects of obesity on health in observational settings (Cawley and Meyerhoefer, 2012; Nordestgaard et al., 2012; Richmond et al., 2014; Smith et al., 2009). Smith et al. (2009) use offspring BMI as an instrument for own BMI in a sample of Swedish parent–son pairs. They conclude that the magnitude of the obesity–mortality association has been underestimated in studies using conventional regression techniques. A similar conclusion was reached by

Nordestgaard et al. (2012) examining the association of BMI and ischemic heart disease in a sample of Danish adults and using genetic variation as an instrument.

Reverse Causation

Perhaps the most discussed challenge in estimating the obesity–mortality association in observational studies is that of reverse causation due to the presence of disease. Many diseases increase the risk of dying and can result in low weight. Diseases for which weight loss is common include many cancers, heart failure, renal failure, and chronic obstructive pulmonary disease (Hu, 2008). Reverse causation results in relative risks for obesity that would be downwardly biased, but the evidence supporting the extent of bias due to reverse causation is largely indirect. One approach has been to eliminate those with preexisting illnesses from the sample. Findings from large epidemiological cohorts in the United States suggest that when those with preexisting illnesses and smokers (who disproportionately experience disease) are eliminated, the relative risks for obesity increase by roughly 20–50% (Adams et al., 2006; Berrington et al., 2010; Calle et al., 1999). Such increases after similar eliminations, however, have not been observed universally (Flegal et al., 2007; Mehta and Chang, 2009). In addition, it is not clear if the removal of large segments of the sample is an effective method of assessing reverse causation as it may introduce additional selection effects that can change the obesity–mortality association independent of reverse causation (Banack and Kaufman, 2014; Flegal et al., 2011; Preston and Stokes, 2014).

Another indirect approach used to account for reverse causation is to eliminate the initial years of prospective mortality follow-up guided by the idea that the biasing effects of reverse causation are most pronounced in the early years after survey collection. A related approach is to allow the relative risks to vary by time in study, which allows for so-called 'time in study' effects. Evidence from studies that have addressed time in study effects is mixed with many studies reporting little to no change in the relative risks for obesity after eliminating the early years of follow-up (Allison et al., 1999; Flegal et al., 2007; Mehta and Chang, 2009). Some studies indicate that the relative risks for obesity grow stronger with increasing time in study (Zajacova and Burgard, 2012).

Alley et al. (2010) using the Baltimore Longitudinal Study of Aging, find that sustained weight loss begins 5–10 years before a cardiovascular death and 3 years before a cancer death in adults ages 60 and over. Thus, although the evidence on how large a role that reverse causation plays is not conclusive, reverse causation should be considered as an important biasing factor, particularly in older populations that suffer from a high burden of disease.

Variations in Relative Risks by Age and Smoking Behavior

Many studies highlight important variations in the relative risks for obesity across population subgroups. I focus here on variations by age and smoking status. The methods used to account for variations in the relative risks for obesity by these two variables have contributed to earlier and more recent controversies over the number of deaths attributable to obesity in the United States (Flegal et al., 2005; Masters et al., 2013b; Mehta and Chang, 2009; Mokdad et al., 2004).

Prior findings from large U.S. cohort studies and other international studies indicate that the relative risks for obesity decline with age (Prospective Studies Collaboration, 2009; Stevens et al., 1998). In fact, it is not uncommon to find that obesity is not associated with excess mortality in older populations (ages 60+) or is protective for mortality (the latter is often termed an 'obesity paradox' and is discussed more fully below) (Prospective Studies Collaboration, 2009). Various explanations have been proposed to explain the declining age pattern. From a biological perspective, body fat is thought to confer physiological advantages during periods of illness (of which older individuals suffer disproportionately from). Relatedly, the biasing effects of reverse causation may increase with age due to a higher prevalence of disease with increasing age.

Masters et al. (2013a,b) argue that the commonly reported declining age pattern is an artifact of cohort differences in mortality risk – related to the fact that the obese in earlier cohorts are likely to have lower durations of obesity compared to the obese in recent cohorts – and age-related survey selection. The latter refers to a specific bias whereby adults with obesity-related morbidities become increasingly less likely with age to participate in health surveys compared to healthier obese adults. I discuss the importance of duration effects in the obesity–mortality association under Obesity Histories.

Alternative explanations for the declining age pattern include competing risks and mortality selection. Competing risks becomes increasingly prominent with age as multiple body systems begin to fail. It is an oft cited explanation for the fact that many other risk factors including smoking also weaken with age. A second reason is mortality selection, a selection distinct from survey selection: among the obese at age x, there is a distribution of unobserved vulnerabilities to succumbing to obesity – the most vulnerable die first, leaving behind a successively less vulnerable group. To date, the role of these alternative explanations has not been investigated and further research is required to understand the relative contributions of all the various explanations put forth to understand why the relative risks for obesity vary by age.

Smoking status is considered an important confounder and modifier of the obesity–mortality association. Smoking reduces weight or otherwise prevents gains in weight in part because nicotine is thought to suppress appetite and increase metabolic demands (Audrain-McGovern and Benowitz, 2011). Smoking is also associated with a high burden of disease.

In the United States, smoking is negatively correlated with obesity (Chiolero et al., 2008). Failure to adequately control for smoking therefore can lead to underestimated relative risks for obesity as smoking operates as a confounder to the obesity–mortality association. In addition to its role as a confounder, smoking behaviors have also been reported to modify the obesity–mortality association. Numerous studies have reported that the relative risks for obesity are lower among current smokers compared to nonsmokers (Adams et al., 2006; Calle et al., 1999; Orpana et al., 2010). The reason for the differential relative risks is not fully explained. Reverse causation bias may play a larger role among smokers because of the high-disease burden in this population. Inadequate control for smoking behaviors is also a plausible explanation.

Often, data on smoking is based on self-reports of smoking behaviors and is amenable to misreporting. In addition to this potential misreporting bias, complete details about smoking intensity and duration are not always available or used in analyses (Hu, 2008). A number of studies report a moderate or otherwise imperfect correlation (0.40–0.70) between cotinine levels, a bioindicator of nicotine presence, and self-reports of smoking (see Stram et al., 2002). These factors would lead to 'residual confounding' of smoking on the obesity–mortality association contributing to the lower relative risks for obesity among smokers compared to nonsmokers. It is important to note that the confounding or modifying role of smoking has been observed to be small or nonexistent in some studies (Durazo-Arvizu and Cooper, 2008; Flegal et al., 2007; McGee, 2005; Mehta and Chang, 2009).

Obesity Paradoxes

The term obesity paradox has been used to describe circumstances in which obesity is found to be protective for mortality. The obesity paradox has been reported in individuals with a wide variety of diseases – kidney disease (Kalantar-Zadeh et al., 2005), heart failure and other heart diseases (Curtis et al., 2005), diabetes (Carnethon et al., 2007), hypertension (Carman et al., 1994), multiple cancers (Gonzalez et al., 2014) – and in older populations (especially among those 70 and over) (Al Snih et al., 2007; Kulminski et al., 2008). Physiological explanations emphasize the protective role of excess fat and are commonly employed in the biomedical literature (e.g., Oreopoulos et al., 2008). Recent evidence, however, suggests that in many cases the paradox is due to a statistical bias. The type of bias is known as 'collider bias' or 'selection bias.' This bias can arise when a sample is 'conditioned' on a common effect of exposure variables as in conditioning on a disease state (Banack and Kaufman, 2014; Glymour and Vittinghoff, 2014; Hernán et al., 2004; Preston and Stokes, 2014). Conditioning a sample on a common effect can change the correlation among exposure variables (Cole et al., 2010). Recently, Preston and Stokes (2014) developed the logic of collider bias in the context of the obesity paradox in a diseased population. They show that the relationship between smoking and obesity (both of which would be 'exposure' variables) is more negatively correlated among those with diabetes ('the common effect') than in the general population (e.g., those with and without diabetes). Using data from the National Health and Nutrition Examination Survey (NHANES), they show that the obesity paradox among those with diabetes is the result of the stronger negative correlation between smoking and obesity in this group compared to the source population that includes both smokers and nonsmokers. Banack and Kaufman (2014) demonstrate that collider bias is also a plausible explanation for the obesity paradox among those with cardiovascular disease (CVD) in the U.S.

The Role of Obesity Histories

Much of the early work on the obesity–mortality association has relied on a single observation of BMI. There has been increasing interest in understanding how weight dynamics over a lifetime influence the risk of mortality (Preston et al., 2013a). Mounting evidence now suggests that there are strong duration effects in the obesity–mortality association. In other words, the longer someone is obese, the higher the mortality risk. For example, Abdullah et al. (2011b) used multiple waves of the longitudinal U.S. Framingham Study and found a positive and dose–response relationship between obesity duration and mortality. In a related analysis, Abdullah et al. (2011a) show a similar relationship of obesity duration and diabetes suggesting that this disease may be an important pathway linking obesity duration and mortality.

Counting the number of years obese is only one method of incorporating weight dynamics in a statistical model. Preston et al. (2013a) provide a detailed typology of the various approaches that have been used when more than one observation of BMI is used in a regression equation. They outlined four specifications that have been most commonly implemented in prior research: additive (i.e., treating each BMI observation additively), duration (i.e., counting the time spent with a high BMI), weight change, and interactive (i.e., including interaction terms among BMI observations). Using baseline and retrospective information on height and weight contained in the NHANES, Preston et al. (2013a) estimated models based on each of the specifications and evaluated the models using two criteria: ease of interpretability and variance of mortality explained. They examined adults ages 50–74 at time of survey and used information on obesity at age 25, age 40, 10 years prior to survey, and at time of survey. Two key conclusions were made. The first is that obesity occurring at various adult ages was equally associated with mortality above age 50. The second is that duration of obesity models performed the best on the two evaluative criteria. The authors additionally found that weight change models, which are frequently used, are not straightforward to interpret. The details of the complexities inherent in interpreting weight change models go beyond the scope of this article and I refer the reader to Preston et al. (2013a) for a fuller discussion.

Mehta et al. (2014) examined the role of obesity histories to mortality at ages 50 and over using the nationally representative Health 2000 survey from Finland. Like NHANES, these data contain retrospectively reported information on weight at earlier adult ages in addition to weight and height collected at time of survey. When Mehta et al. (2014) compared their estimates from Finland with those reported by Preston et al. (Preston et al., 2013a) using the U.S. NHANES, they found that the association between obesity duration and mortality is remarkably similar in both countries (ages 50–74 at time of survey). Mehta et al. (2014) also examined the role of 'peak BMI' as an element of weight histories. Peak BMI refers to the highest BMI attained in life or is otherwise available in data regardless at what age it occurs. In Mehta et al. (2014), peak BMI was identified by the highest BMI recorded at ages 20, 30, 40, 50, and at time of survey. Mehta et al. (2014) found that peak BMI is significantly and positively associated with mortality even in the presence of BMI at time of survey. In fact, the excess risks of obesity using a measure of peak BMI appear double than that of using baseline BMI when each is considered in separate models. The hazard ratios for those

whose peak BMI was $\geq$30.0 kg m^{-2} was 1.42 (95% CI: 1.04, 1.95) relative to those whose peak BMI was less than a BMI of 25.0. The hazard ratio for obesity (BMI $\geq$ 30.0) at time of survey was 1.22 (95% CI: 0.91, 1.65) relative to a BMI < 25.0 at time of survey. The authors also found that peak BMI was moderately and positively correlated (rho = 0.62) with obesity duration.

A key strength of peak BMI is that it may be more robust to reverse causation compared to BMI at time of survey because peak records the highest achieved weight, which is not directly influenced by subsequent weight loss due to disease. Another advantage of peak BMI is that it can be efficiently collected in health surveys, even in instances when more complete histories cannot be collected. Mehta et al. (2014) concluded that peak body weight be regularly collected in health surveys and used to assess the obesity–mortality association.

The sharp period increases in obesity that many nations have experienced suggest that there are important birth cohort differences in obesity histories and obesity duration (among the obese and for the cohort as a whole). Compared to earlier cohorts, the most recent birth cohorts have been experiencing high levels of obesity at young ages. The finding by Preston et al. (2013a) and others that obesity in early adulthood is consequential to later life mortality indicates that obesity has already left an imprint on the future mortality experience of recent birth cohorts. Moreover, the use of peak BMI to estimate the number of deaths attributable to obesity will likely yield a much larger role for obesity than estimates based on BMI at time of survey. Using recent NHANES data, Stokes (2014) found that among those ages 50–84, the number of deaths attributable to a BMI $\geq$ 25.0 was 33% when it was calculated based on peak BMI compared to only 5% when calculated based on BMI at time of survey. Nearly all prior estimates on the number of deaths attributable to obesity have been based on BMI at time of survey.

The recent findings on the role of obesity histories has important relevancies to understanding the extent to which obesity is influencing aggregate levels of mortality in the future. Preston et al. (2013b) project both current obesity and obesity at age of 25 years by birth cohort to examine how rising obesity will affect life expectancy in the United States through 2040. The authors estimate that rising obesity will have a reducing effect of 0.73 years (males) and 0.82 years (females) on life expectancy at age of 40 years through 2040. This reducing effect of obesity represents approximately 29% (males) and 38% (females) of the projected growth in life expectancy during this period as forecasted by the Social Security Administration.

Obesity and Mortality in an International Context

There has been little work examining the role of obesity in contributing to international differences in mortality. Of particular interest has been the role that obesity is playing in contributing to the shortfall in U.S. longevity relative to other high-income countries (National Research Council, 2011). The United States has the highest levels of adult obesity among OECD nations (OECD, 2013). Using relative risks for obesity from NHANES, Preston and Stokes (2011) estimated that obesity is responsible for reducing U.S. life expectancy at age of 50 years by 1.54 years (men) and 1.85 years (women) in 2006. This reduction accounted for 42% (men) and 67% (women) of the U.S. shortfall in longevity at age of 50 years compared to other high-income countries with higher life expectancy at this age. To date, there has been little examination of whether the relative risks for obesity vary across countries. As described above, the findings by Mehta et al. (2014) indicate that the role of obesity duration in shaping mortality risks is remarkably similar in Finland and the United States. This cross-national comparability suggests that obesity is operating similarly on mortality in countries with relatively advanced obesity epidemics. Further cross-national comparisons of the relative risks for obesity will help identify the role obesity is playing in aggregate mortality patterns and in contributing to cross-national differences in longevity.

Another important consideration is the contribution of obesity to socioeconomic differences in mortality within countries. The strength and direction of the relationship between BMI and socioeconomic status varies considerably across countries with both positive and negative gradients observed (McLaren, 2011; Subramanian et al., 2013). In the United States, obesity is inversely associated with education (Sanchez-Vaznaugh et al., 2009) and income (Chang and Lauderdale, 2005) among women. Gradients tend to be flatter among U.S. men. The role that obesity plays in contributing to socioeconomic differences in mortality within countries has been an understudied area. In contrast, cigarette smoking alone has been shown to explain up to 50% of educational differences in male mortality in Europe (Jha et al., 2006). Using data from the Whitehall II study, Stringhini et al. (2010) report that four health behaviors (smoking, alcohol consumption, diet, and physical activity) explain approximately 70% of mortality differences between the highest (administrative) and lowest (clerical or support) occupational grades (ages 35–55) in this cohort. Of this, diet and physical activity jointly accounted for approximately 20% of the difference after accounting for the other behaviors. Using the nationally representative American Changing Lives Study, Lantz et al. (2010) report that physical inactivity and high BMI, along with smoking and alcohol consumption played a small role in explaining income and educational disparities in mortality among U.S. adults (ages 25+). Further work on the specific contribution of obesity to socioeconomic mortality differentials is required.

Secular and Cohort Changes in the Obesity–Mortality Association

Whether the relative risks of obesity have been changing over time also has important implications for the current and future aggregate mortality effects of obesity. To date, most studies examining secular or cohort changes have focused on the United States. Flegal et al. (2005) show that the relative risks for obesity appear to have declined among younger- and middle-aged adults (<70 years) over some successive NHANES surveys. Mehta and Chang (2011) show that there also appears to be a decline since the 1970s and 1980s

among middle-aged samples from NHANES, the U.S. National Health Interview Survey, and the U.S. Framingham Heart Study. One potential explanation or the declining relative risks is that the obese have disproportionately benefitted from improved treatments of cardiovascular risk factors, most notably hypertension and high cholesterol, relative to the nonobese (Gregg et al., 2005). Nonetheless, the decline in relative risks in the United States has not been observed universally. Calle et al., (2005) reported no decline in the relative risks of obesity among adult nonsmokers between 1982 and 1998 in the U.S. Cancer Prevention Study II. Yu (2012), also using NHANES, examined age, period, and cohort variations in the relative risks for obesity and concluded that the relative risks increased from earlier to more recent cohorts with no apparent secular decline among adults born between 1901 and 1957. The studies examining secular or cohort changes in the obesity–mortality association have not directly modeled the role of changes over time (or over cohorts) in obesity duration among the obese. The rapid increase in obesity prevalence in the U.S. and elsewhere may have led initially to a decline in the average duration obese for an obese person. However, such a change has not been confirmed empirically. In addition, many high-income nations are experiencing a 'behavioral replacement' away from smoking and toward higher obesity (Flegal et al., 2010; Giskes et al., 2005; Preston et al., 2013b). It is not fully understood how changes over time in the smoking composition of populations is influencing the relative risks for obesity.

Conclusion

My objective in this article was to highlight both advancements and continued areas of uncertainty in understanding the obesity and mortality association. Despite the large volume of research, many methodological concerns and controversies about its estimation remain. Recent work that has modeled weight dynamics over the life course have undoubtedly advanced our understanding of this complex association. So too has research highlighting the potential statistical biases that can arise in estimating the obesity–mortality association. Nonetheless, there are many avenues for continued research. These include a clearer understanding of the long-term effects of high levels of early life obesity in recent cohorts and the potential beneficial effects of weight loss and weight loss interventions among adults who have already experienced a long duration of obesity. We will also benefit from a clearer understanding of whether the obesity–mortality association is similar in different countries and contexts and whether secular or cohort changes are occurring. Moreover, there has been comparatively less research in developing countries whose populations also continue to experience concomitantly high levels of undernutrition (one exception is Zheng et al. (2011) who provided a comprehensive study of Asian populations).

Obesity: Cultural and Biological Factors

Alexandra A Brewis, Arizona State University, Tempe, AZ, USA

Abstract

Humans are evolved to gain weight easily under the conditions of plenty and maintain weight when food supplies are insecure. Globalization of low cost and readily available calories alongside changes in work and built environments that encourage sedentism has led to obesity as a common condition in many parts of the world. Obesity is also increasingly associated with poverty and social and structural disadvantage within countries. Despite obesity being identified as one of the most critical contemporary public health challenges, standard interventions to address it have often failed and both child and adult obesity rates continue to rise around the world. Cultural, biocultural, and ecological theories help explain both the rise of obesity and the resistance to any easy fixes. Social theories provide critical perspectives on the medicalization of obesity and challenge pervasive views of obesity that treat it as a sign of individual moral failing.

Introduction

Obesity technically refers to an excess amount of adipose tissue (body fat). While the way in which 'excess' is defined is often arbitrary (Romero-Corral et al., 2006), common clinical and scientific practice is to label an adult as obese, if their body mass index (BMI: weight/height^2) is 30 or higher. This cut point is considered to roughly match the level of body mass at which health starts to be noticeably compromised (Mascie-Taylor and Goto, 2007), placing people at heightened risk of such diseases as type II diabetes, hypertension, and heart disease. But several studies also show that many 'normal' weight people have metabolic profiles with high triglycerides, blood pressure, or insufficient insulin response that are considered a corollary of being obese, and that it is often fitness level rather than fatness level that counts (McAuley and Blair, 2011; Ruderman et al., 1998).

Using the standard definition of obesity represented by a BMI of 30 or more, currently over one-third of adults are obese in the United States, and proportion is even higher in some low-income nations. The only major world region that is yet to see the emergence of noticeable overweight and obesity in adulthood is north and east sub-Saharan Africa (**Figure 1**). Of the industrialized nations, the Nordic countries and Singapore stand out as having comparatively low rates. While rates in the industrialized North have been growing over the last several decades, adult and child weights in many low-income countries have begun accelerating more recently, and at a much faster pace (e.g., China, see Popkin, 2008). Recent projections suggest that if current trends continue, over half of US adults will be obese by 2030, and that low-income and high-income countries alike will be devastated by attendant disability and lost work productivity within a generation (e.g., Popkin, 2009).

Ecological Models of Obesity

Most fundamentally, the rise of obesity represents a growing and chronic imbalance between calories consumed and expended. With the globalization and commercialization of food systems since World War II, cost-effective foods that are high in fat, salt, and sugars have increasingly dominated diets throughout the world (Popkin, 2009). In many countries, growing household wealth has also allowed for greater food purchasing. With urbanization, changing transportation practices, new technologies, and increasing occupational sedentism, everyday exercise levels have at the same time decreased markedly for many (Dufour and Piperata, 2008).

Specific population case studies have demonstrated how these types of lifestyle changes have played out historically and in local ecologies to lead to rapid escalations in obesity risk. In comparing Samoa and American Samoa, where populations are genetically highly similar, McGarvey and

Figure 1 Prevalence (%) of obesity (BMI $\geq$ 30) in women over age 15, 2010 by country. Source: World Health Organization Global InfoBase.

colleagues (McGarvey, 1992; McGarvey et al., 1993, 1989) have shown how temporal changes in occupations (from farming and fishing to office work, for example) and diet (such as a move away from traditional diets) together promote very rapid growth in obesity risk at the population level within one generation. Carolyn Smith-Morris' (2004, 2006) historical study of the Gila River Akimel O'odham (Pima) of central Arizona shows how political, ecological, and cultural factors can force institutional changes (such as emergence of new dietary traditions, or health care practices) that spur rapid – and seemingly intractable – increases in obesity risk.

Many social science approaches thus recognize some social ecological environments as being 'obesogenic' and others as 'leptogenic' (Egger and Swinburn, 1997). This ecological approach to obesity is gaining traction within public health and emphasizes the normality of gaining weight when living in certain environments. It also suggests that neighborhood-level ecological change is the best way to reduce obesity risk in populations. A wide array of studies in geography and related fields have shown the effects of variations in built environment on obesity risk. For example, neighborhood walkability (influenced by such factors as road structure and repair, types of destinations available and proximity, and safety) makes a big difference to how much people living in cities walk (Rundle et al., 2009). Parks provide an important venue for both formal and informal exercise, and park access similarly is unevenly distributed; higher income areas tend to have better parks (more accessible, safer, better facilities) (Cutts et al., 2009; Saelens et al., 2003). People who live near parks or good physical fitness facilities in cities are shown to get significantly more exercise than those who do not (Giles-Corti et al., 2005; Gordon-Larsen et al., 2006) and child obesity rates are suggested to be significantly lower where access to green spaces is better (Sallis and Glanz, 2006). People's perceptions of environments, for example, as safe and pleasant, can be just as important in shaping neighborhood exercise patterns as actual amenities (Humpel et al., 2002; Timperio et al., 2005).

Cityscapes have uneven distributions of access to healthy, fresh, and affordable foods that make it easier or harder to eat an optimal diet (Gallagher, 2006; Horowitz et al., 2004; Morland et al., 2002; Powell et al., 2007; Sloane et al. 2003). Given the way cities develop, favoring the needs of the powerful, areas of low walkability and so-called food deserts are often clustered in lower income and minority inner city neighborhoods. These areas are often correspondingly filled with fast food advertising and restaurants.

The uneven distribution of worse exercise and food amenities in lower income and minority neighborhoods makes obesity risk an 'environmental justice' issue for some (Taylor et al., 2006; Cutts et al., 2009), and provides one explanation why minorities can be at higher risk of obesity even once socioeconomic factors are taken into account (Chang, 2006; Robert and Reither, 2004). Studies of built environment factors in low-income countries reveal patterns that are very different from that typically observed in high-income countries; for example, Mowafi et al.'s (2012) analysis of Cairo shows no significant association of access to green spaces with BMI variation.

Genetic and Epigenetic Explanations of Obesity

To add to the complexity of the historical and environmental picture, body mass and fat distribution patterns show heritability. A recent meta-analysis that pooled genetic data from 249 796 participants identified or confirmed 32 loci in different parts of the genome that helped explained susceptibility to high vs low body mass (Speliotes et al., 2011). Overall, the effect was noticeable but also modest – people with a large number of these variants were 15–20 pounds heavier than those with few of them (Speliotes et al., 2010). Epigenetic models, which focus on how genetic and environmental factors interact across generations to create variation in obesity risk, are increasingly seen as a compelling way to explain historical patterns of rapid escalations of population-level weight gain and obesity in the contexts of these genetic variants. Gluckman and Hanson (2005) coined the term "predictive adaptive responses" to describe important evolved mechanisms that allow humans to adapt to conditions in which food supplies are low or unpredictable. So, when children from low nutrient levels *in utero* suggestive of environmental insults, the body responds to this phenotypically by developing a lower metabolic rate and smaller body build – a so-called thrifty phenotype. This complex of features is advantageous under food-insecure or food-short conditions, but then predisposes via several different pathways to greater weight gain or reduced weight loss when people encounter calorie rich environments during childhood and adulthood (Kuzawa, 1998).

Demography, Socioeconomics, and Obesity

Within countries, states, and cities, there are major demographic variations in obesity, such as by gender, ethnicity, and immigrant status. In most national samples, there is a preponderance of female obesity compared to male (Mascie-Taylor and Goto, 2007) that is at least partially explained by social constructions of gender that shape daily exercise patterns (e.g., the roles of farmer vs housewife) (Brewis, 2011). Minority status, is often discussed in the United States as a major determinant of risk. For example, African-Americans and Mexican Americans are often reported to have the highest rates of obesity (Wang and Beydou, 2007). While relative wealth explains some variation in risk, the patterns are different across these groups; for example, Mexican American women living in poverty are the highest at risk within Mexican Americans, but among African-American men, those who are wealthier are more at risk (Walker and Kawachi, 2011). In response to these diverse findings, many interventions are targeted for subgroups and focus on different ecological and cultural explanatory models of how obesity risk accumulates.

Socioeconomic status (SES) is one of the best predictors of obesity risk within countries. Currently, the higher one's SES in a low-income country the higher BMI is likely to be, and the lower one's SES in a wealthy country then the higher BMI is likely to be (see Brewis, 2011). In 1989, Stunkard and Sobol published an oft-cited summary of 144 studies conducted in

1960s–80s. They described a basic pattern at that time whereby men, women, and children in lower- and middle-income countries were more likely to be overweight if they were socioeconomically advantaged. Newer transnational theories, considering how wealth differentials themselves affect obesity, propose that liberal market economic regimes (like the United States) act to proliferate obesity risk, especially when compared to more regulated welfare economies (like Sweden and Norway) where the wealth gap is narrower (Offer et al., 2010).

A different way to understand how socioeconomic context influences obesity comes from examining social networks – that is, people's everyday webs of social connections. The seminal study in this area by Christakis and Fowler (2007) used longitudinal data from the Framingham Heart Study to show that those whose associates (especially mutually close same-sex friends) gained weight also tended to gain weight themselves. Thus, over time, obesity tends to clump within social networks (as does slimness). Although the clumping itself has been shown in other studies, the underlying mechanisms are not well understood. While Christakis and Fowler posed that shared norms might be responsible, other studies have suggested that this 'social contagion' model is not the best explanation. For example, Cohen-Cole and Fletcher (2008) suggest shared environments are sufficient to explain the convergences in weight over time; Hruschka et al. (2011) show that – even though clustering could be confirmed – shared norms only accounted for 20% of the convergence observed (mainly through influences on ideal body image).

Cultural Meanings of Fat Bodies

Bodies are imbued with cultural meaning in all human societies and what people consider the ideal profoundly reflects and shapes identities and the broader social order (Brown and Konner, 1987; Brown and Sweeney, 2009; Douglas, 1970). A number of ethnographic studies conducted in the 1980s and 1990s have detailed social contexts in which women's fat bodies express beauty, marriageability, attractiveness, and an array of positive moral attributes such as control of selfish desires, closeness to God, generosity, fertility, familial responsibility, and social belonging (e.g., Brown and Konner, 1987; Brown and Sweeney, 2009; Popenoe, 2004; Sobo, 1994). An important example is Popenoe's (2004) study with Azawagh Arabs in Niger, in which she demonstrates how women use large bodies, rolled with fat to advance their social and economic goals, such as through better marriage. An ethnographic survey of several cultures by Brown and Konner (1987) suggested that the majority of human societies traditionally preferred plump women's bodies, in sharp contrast to the prevalent values placed on slimness in the West in the last several decades.

In industrialized contexts, best documented for the United States, women's bodies have long been the dominant, preferred, and inescapable symbol of their self and identity (Becker, 1995: p. 33; Degher and Hughes, 1999; Rubin et al., 1993). The writings of Becker (1995) and Martin (1989) explain how the body has emerged as 'something to be worked on.' Bordo's interpretive analysis discusses the importance of a slim – and for many unobtainable – female body as the cultural expression of an individual's mastery over their desires. Slimness is associated with self-discipline and control, but also health, beauty, intelligence, youth, wealth, attractiveness, grace, and goodness (Caputi, 1983; Moreno and Thelen, 1993). Fatness and obesity are by contrast associated with ugliness, sexlessness, and undesirability, but also with specifically moral failings such as a lack of self-control, social irresponsibility, ineptitude, and laziness (Becker, 1995; Cordell and Ronai, 1999; de Garine and Pollock, 1995; Martin, 1989; Stunkard and Sobal, 1995; Turner, 1984). For women in particular, a 'fat' body can trump *all* other aspects of identify formation (Carryer, 1997; Bordo, 1993), explaining in cultural and social terms why the emotional suffering around the experience of 'being fat' can be so devastating. Sociological studies of 'weight identities' have shown that people recognize and interpret a vast array of complex cues to determine if they are 'fat' (Degher and Hughes, 1999). After significant weight loss, while many describe social 'rebirths,' those of both genders with 'fat' identities can also find themselves struggling with their new 'thin' ones, often presaging weight regain (English, 1993; Granberg, 2006).

Weight Stigma and Discrimination

The social stigma that attends moral judgments about fat bodies explains the high rates of discrimination reported by the largest members of society in the United States (Puhl and Heuer, 2009; Sjoberg et al., 2005). The technically obese (those with BMI over 30) have less career and educational access, lower pay, worse health care service, and are significantly more likely to be fired, bullied, teased, and romantically rejected (Puhl and Heuer, 2009 provide a literature review). Given the predominant cultural model that individual moral failing underlies weight gain, public health and clinical approaches often place the 'blame' for failure on the individual. It seems that even the slim understand the very profound social costs of obesity: based on surveys of trade-offs people are willing to make to avoid obesity, many Americans say they would rather die younger or be blind than be obese (Schwartz et al., 2006).

Weight stigma has the dubious honor of underpinning what some have identified as the last socially acceptable form of discrimination (Puhl and Brownell, 2001). Anticipating or experiencing discrimination, because it challenges core social identities and often takes a chronic form, can prove a very powerful potential source of stress-induced pathophysiology/physiological responses (McEwen, 1998; Gravlee and Dressler, 2005), and this is a potentially important but as yet little studied aspect of obesity etiology (Rosmond and Bjorntop, 2000).

There appears to be a major global trend toward increasingly negative cultural and normative views of large/fat bodies. Using cultural survey data from 11 different locations globally, Brewis et al. (2011) reported that the highest levels of antifat attitudes were measured in middle income nations and territories, such as Paraguay and American Samoa. Anne Becker's work in Fiji shows that exposure to such new media,

such as television quickly changes how people view their large bodies in the context of self and society, moving them toward a slimmer ideal and away from the traditional notion that a sense of self was shaped by community membership rather than individual body habitus (i.e., as the embodiment of culture and ritual daily practices) (Becker, 1995, 2004). Based on recent work in Belize, Anderson-Fye proposes that participation in a transnational economy, drive for success in that new economy, and changing dietary options have introduced eating disturbance and awareness of body size and control among youth (both male and female, although most so for women): the slimmer women have more opportunity afforded to move into the higher paying tourism industry because they adhere to tourist body ideas, rather than local one (Anderson-Fye, 2004; Anderson-Fye and Lin, 2009). Based on a study of urban Paraguayan women, Brewis and Wutich (2012) pose an essentially reverse possible pathway: that changing body norms leads to fat stigmatization that then erodes both material and social capital and promotes weight gain.

Critical Perspectives

Obesity is a good example of a human condition that has become increasingly medicalized over the last several decades; meaning it is defined, discussed, and treated predominantly as medical problem (Sobal, 2011), such as through surgery or pharmacology (Sadler et al., 2009). Medicalization can be helpful in reducing stigma where it deemphasizes the role of individual responsibility, yet it also can promote stigma by labeling all obese bodies as a sick, regardless of the actual health of the individual.

Some social scientists have suggested that obesity in modern contexts is a form of 'moral panic' in which massive global alarm over obesity 'time bombs' and 'epidemics' speaks more to the ways in which obesity is thought to damage society, rather than good scientific evidence. Thus, the obesity epidemic is argued by some to be largely a fabrication that allows powerful groups (such as the commercial diet industry) to promote their own interests by selective use of evidence (Campos et al., 2006). The work of Marilyn Wann and others in the field of fat studies argues prevailing cultural ideas about fat as a form of oppression in itself, especially when the demography of obesity intersects so clearly with race/ethnicity, gender, and poverty (Rothblum et al., 2009). Scholarship in this area reveals alternative cultural models where negative ideas around fat are contested, and positive identities related to 'fat' are being promoted – such as the idea of a fat body as rebellious. This approach as has emphasized the importance of recognizing competing 'frames' – ways of understanding that provide and focus meaning, such as the competing explanatory models used by medically oriented obesity researchers vs fat acceptance activists (Saguy and Riley, 2006).

Obesity as a Complex Problem

After several generations of failed weight loss advice that focused on the importance of individual effort around dieting and exercising as the panacea, increasingly obesity is understood to be much more of a 'wicked problem' – tied in incomplete, complex, and often contradictory ways to changes in local and global ecological, economic, and political systems (not just around food), our urbanizing and increasingly built environments, our technological and social fixes, deeply imbedded in cultural context, and deeply imbedded in our psyches and psychologies, and all in ways that are difficult to recognize and certainly seemingly impossible to fix in any singular or straightforward manner. Systems science provides a means to bring these multiple aspects of obesity into a more comprehensive view that can move across different levels of analysis (Gortmaker et al., 2011). That is, systems models can incorporate the socioecological models already widely applied to include the complexity of myriad proximate and distal factors connected through tipping points and feedback loops and in nonlinear relationships (Finegood, 2011). In this way, the obese body is an emergent property of myriad interplaying factors. A further advantage of a systems approach is that the environmental and contextual causes of obesity tend to become the focus, rather than framing obesity as a product of individual behaviors or more particularly individual moral failings.

Conclusion

While the number of obese people rises globally, the topic of obesity remains ambiguously articulated in scholarly discussions in the social sciences. This includes ongoing and unresolved debates about when and how to define obesity as a 'problem.' Yet, as global public health campaigns gear up to take on the growing 'epidemic' of obesity throughout the world, basic and translatable knowledge about the social bases of obesity is critically needed. Particularly, social science studies to date suggest the better approach to curtailing population obesity is through comprehensive institutional transformations, such as in the built environment and social norms, rather than through individual behavioral or medical intervention.

Abstract

This article discusses what objectivity is, and the challenges that have been leveled against the idea that we can attain objectivity. (1) Possibility of objectivity: objection of ancient Pyrrhonists that everything is subjective, and how it might be met. (2) Relativity of objectivity: Why the fact that everything is relative to judgment or interpretation is not a problem. The question of observers affecting what they observe. (3) Objectivity in the natural and the social sciences: explanation vs interpretation. Could there be different kinds of objectivity, or just different ways in which we might establish objectivity. (4) Cases of conflict between theory and evidence: there is no hard rule on when the theory should be revised to accommodate the new evidence and when it should be abandoned.

Although the term 'objective' only came to have its modern sense in the eighteenth century, issues bound up with objectivity have been rife since seventeenth-century disputes over the respective merits of accounts based on facts and those relying on deductive argument (see Daston, 1992, 1994). Objectivity stands in contrast to subjectivity: an objective account is one which attempts to capture the nature of the object studied in a way that does not depend on any features of the particular subject who studies it. An objective account is, in this sense, impartial, one which could ideally be accepted by any subject, because it does not draw on any assumptions, prejudices, or values of particular subjects. This feature of objective accounts means that disputes can be confined to the object studied. But since there must be some input from the subject in terms of theories, assumptions, etc., this is possible under two conditions: neutral assumptions and shared assumptions. The first is obviously preferable to the second (because the shared assumptions might be mistaken), but there are questions as to whether the first is possible only in a limited range of cases, whether it is possible at all, and whether the second is possible in all, some, or no cases.

Much recent literature in the social studies of scientific knowledge effectively denies that either of these is possible, and argues that if we are to understand how scientific projects come to be accepted, we need to examine not their purported objectivity or truth but the rhetorical strategies employed by their proponents (see the discussions in Fuller, 1993; Golinski, 1998; and the essays in Megill, 1994; *see* Scientific Knowledge, Sociology of). Concern with the nature and possibility of objectivity is not new, however, and by looking at some traditional questions that have been raised about objectivity, we can attempt to identify what is genuinely problematic about objectivity and what is not.

The nature of objectivity can best be brought out by considering challenges to it. There are three traditional kinds of challenge that bring out some of the principal issues: the claim that objectivity is impossible; the claim that objectivity is always relative; and the idea that the form objectivity takes in the natural sciences might not be generalizable.

Is Everything Subjective?

The ancient Pyrrhonists denied that objectivity was possible (see Annas and Barnes, 1985). Everything, they argued, is relative to the observer, to the conditions under which the observation is made, and to the state the object is in when it is perceived. For example, what color we observe something to be will depend upon us – it will look different depending on whether we have jaundice or not – upon the medium in which it is observed – it will depend upon whether we observe the object through air or red-tinted glass – and it will depend upon the state of the object – such as whether the object is in a solid form or a powder (gold is yellow when solid and white when powdered, for example). Observation is always inescapably relative to a host of factors and not only can we not avoid this relativity, but, the Pyrrhonists argued, we cannot single out any factor as being objective. There is no objective fact of the matter as to what color something is, or even whether it is moving or stationary, large or small: it depends on the circumstances of viewing and we have no grounds for preferring observations made by a stationary observer to those of a moving one, those of a close observer to those of a distant one, or even those of an intoxicated observer to those of a sober one.

Now even if we were to accept that there are never any optimal viewing conditions (remembering that these kinds of argument often work by choosing examples where there are no optimal viewing conditions, and then moving illegitimately to the claim that there are *never* optimal viewing conditions), we would not thereby be forced to dispense with objectivity. An objective theory can predict how a powder will look when viewing through different colored glasses, how something will look if we have jaundice, and it may predict color changes when a solid is ground into a powder; and we can certainly correlate changes in perceived speed with our state of motion, even our state of motion relative to one another. In other words, an objective theory is not one that simply chooses one set of viewing conditions over others and then stipulates that these will be the objective ones: it is one that holds for all viewing conditions, and any choice of one set over others does not affect the objectivity of the claims of the theory.

Is Everything Relative?

Any perceptual judgment involves, as well as input from the object perceived, various inputs from our perceptual and cognitive faculties, and we might reasonably expect this latter type of input to take on an increasingly significant role as we move away from straightforward observation. What we see and what we judge is, therefore, dependent on various perceptual-cum-cognitive interpretations that we place on our observations: there is no such thing as a 'view from nowhere' (see Nagel, 1986). This does not rob these observations of objectivity. To think this is to assume that objectivity can be secured only in the absence of interpretation and judgment, but the question of objectivity does not even arise in the absence of these. Objectivity becomes an issue when we raise the question of the standing of our judgments and interpretations. We are not seeking a view from nowhere: we are seeking interpretations and judgments that hold up against all alternatives when judged by the same criteria. The fact that judgments involve conceptual structuring and interpretation (conceptual structuring and interpretation which might have been different) in itself has no bearing at all on the objectivity of those judgments.

The trouble is that when we move beyond this, to the question of theoretically motivated or theoretically guided interpretations of phenomena, differences in these interpretations may result in differences in what counts as evidence, differences in what counts as demonstration, and in what counts as a satisfactory explanation (see Kuhn, 1970; Gaukroger, 1978). Here we do face problems of objectivity. In such cases, questions may well arise of whether, in not treating a particular kind of evidence as revealing, for example, one is being objective. Now failure of objectivity may be very difficult to decide in such cases, but we must not confuse failure of objectivity with differing standards of objectivity. Kuhn's work, in particular, has sometimes been read in such a way that the move from one paradigm to another is akin to a religious conversion rather than something objective (Kuhn himself used this analogy, but arguably as a way of capturing the phenomenology of the experience of moving from one paradigm to another, not as something that was intended to throw light on how changes to the content of science are made). There may indeed be paradigm shifts that reflect no objectivity and are like religious conversions, but the ones that Kuhn described, which are very much the success stories of the physical sciences, are clearly not of this type: the move from Aristotelian to Newtonian to Einsteinian cosmologies is a progression with a clear rationale in terms of objectivity, which a move in the opposite direction, for example, would not be.

Genuine cases of different standards of objectivity are difficult, if not impossible, to find, but those who have tried to establish a relativity of objectivity to the investigators' beliefs or theories or values have sometimes invoked two cases in twentieth-century physics – relativity theory and quantum mechanics – which seem to provide examples of the relativity of observational results with respect to the observer. In fact, they do not. In the relativity case, what Einstein showed in his Special Theory was that we have to alter our assessment of what is relative and what is fixed, but no increase in relativity, as it were, results from this. In classical physics, it had been assumed that how quickly a body is moving will appear differently to different observers: if one is traveling in the same direction as the body, for example, it will appear to be moving more slowly than if one passes it traveling in the opposite direction. In other words, velocity is relative to the observer. But the speed of light in a vacuum turned out to be constant no matter in what direction, or at what speed, the measuring apparatus was moving. Einstein argued that the only explanation for this was that the speed of light was constant, but that space and time contracted or dilated depending on the direction and speed of the observer. Space and time, which were previously absolute, are now made relative to the observer (but not merely relative: they really do – objectively – dilate and contract!), but the speed of light, which was previously relative to the observer, is now made absolute.

The case of quantum mechanics is rather more complex, but again we cannot draw any general conclusions about the relativity of observations from it. The quantum mechanics case arises because we cannot measure both the position and momentum of a particle: measurement of one affects the other. One early interpretation of this phenomenon, the Copenhagen Interpretation, maintained that particles were not in a physical state when not being measured: it was the act of measurement, which involved an interaction between a measuring apparatus and a measured system, that put them in a physical state. Moreover, in the Copenhagen Interpretation, this interaction is very problematic and peculiar because the measuring system obeys classical laws, whereas the measured system obeys quantum laws. The lesson that some have drawn from this is that measurement or observation affects the system observed, so we can never know what the system would be like without the observation or measurement, which is what we seek to know.

The peculiarities of the quantum mechanics case make it difficult to understand even in its own right, but this has not prevented some from trying to take it as a general model. Making a very contentious interpretation of something which is poorly understood into a source of guidance is clearly foolish. Nevertheless, does there not seem to be an analogy between this case and one that may arise in the observation of human behavior, for example, where the fact of being observed might inevitably and perhaps unconsciously lead one to modify one's behavior? The analogy breaks down, however, because the case of modification of behavior is something which we can develop techniques for dealing with, whereas this is explicitly not possible in the Copenhagen Interpretation. Such techniques have been around since antiquity, and were developed in the sixteenth century in the context of legal and historical testimony in a particularly interesting way (see Franklin, 1963). Francesco Patrizzi, in his *Dialogues on History* of 1560, had attempted to show that the historian can either be impartial, or informed, but not both. He begins by rejecting secondary sources as virtual hearsay, and he divides primary sources into the partisan and the objective. Then, replying on a number of Machiavellian assumptions about the nature of rulers, he sets up a dichotomy between the partisan observer and the objective

observer. Partisan observers – in this case, those sympathetic to the ruler – in virtue of being partisan, have access to the relevant information, because the ruler can rely upon them; but because they are partisan they will not provide an objective rendering of this information. Objective observers, namely those who are prepared to be critical of the ruler if this is merited, on the other hand, will not, because they are objective, have the ruler's confidence, and so will not have access to the source of the relevant information. (If this seems farfetched, just think of the widespread practice of government briefings to selected journalists.) Patrizzi's conclusion is that it is "utterly and totally impossible for human actions to be known as they were actually done". The response from his contemporaries was that there are a number of ways in which we can establish credibility and plausibility, along the lines applied in law where, for example, we have doubts about a witness' credibility. In such cases we take into account such factors as the probative value of reinforcing testimonies: the problem is not one of a skeptical challenge to the objectivity of history per se but rather problems about evidence and reliability which practitioners of the discipline will usually be best placed to deal with. The same range of solutions is available to the anthropologist or psychologist, for example, who is concerned that the observation of his or her subjects causes them to modify their behavior or statements in some way.

Does Every Type of Explanation Call for Objectivity?

Objectivity seems to require us to stand back from the phenomena we are examining, as it were, so that we can investigate and assess them from a wholly impartial standpoint, which could be used for any phenomena of this kind. It is not always clear, however, that this approach is either the only one, or the most informative one. Consider the case of an anthropologist studying a rain dance. Assume that rain dances do not actually cause it to rain, and have never done so, yet are always performed at times of drought, and assume that there is evidence that, in times of drought, social strife and uncertainty about the nature of authority increases. In this case, it seems reasonable to answer the question why the natives perform the rain dance in functionalist terms, namely that the rain dance secures social cohesion. But there is also a sense in which this is a wholly inappropriate explanation: the natives perform the rain dance only when they want it to rain, and their reason for performing it is clearly because they believe that this will increase the chances of rain.

There are three kinds of response one can make to this issue. The first is to insist that only the first explanation is objective and impartial. It requires us to stand back from the phenomena and treat them as we would any other: after all, functional explanations can be given for phenomena in our own societies – one can imagine a functionalist explanation of regular presidential or parliamentary elections as securing social cohesion, for example – as well as in others. The theory it works with is something that has been developed in such a way as to eradicate partiality and the imposition of the values of its advocates. Generally speaking, one crucial thing that we seek in scientific explanations is algorithmic compression; that is, particularly economical statements of the principles underlying data that enable us to generate that data and predict outcomes. The functionalist criterion meets this requirement in a way that the account which sticks to what the participants themselves believe does not.

The second response is to argue that the issue hinges on the fact that the functionalist account fails to – indeed cannot but fail to – capture the thought that motivates the participants in the dance. One way in which this contrast is sometimes expressed is in terms of the distinction between reasons and causes: giving the reasons someone has for doing something (or interpreting the behavior) and giving the causes of their behavior are two different things. Some philosophers – most notably Vico and Dilthey – have argued that the natural sciences and the *human sciences* (*see* Human Sciences, History of) are quite distinct (see Berlin, 1976; Dilthey, 1976; Ermarth, 1978) in this respect. In particular, while it might be appropriate to 'stand back' from phenomena in the natural sciences to achieve objectivity, this is inappropriate in the case of the human sciences, where we are dealing not with an objectified realm, but with human beings who have intentional states, emotions, exercise judgment, etc., things they share with the investigator and which the investigator is therefore in a position to interpret and make sense of: something quite different from what we do in the natural sciences. In this view, to take the functionalist road would be to treat the rain dance as if it were on a par with a natural, nonintentional phenomenon and it would thus fail to appreciate the nature of the phenomenon under investigation. Proponents of such a view are not denying that objectivity in the sense of impartiality is appropriate in the human sciences, but rather that criteria of objectivity, or guides as to how objectivity might be achieved, can simply be imported from the natural sciences, because what is at stake is not the discovery of causes but the interpretation of behavior. Similarly with a third response, which denies that there is just one way of explaining the rain dance: different accounts bring to light different aspects of the phenomenon. The success of an explanation on this account is relative to what one wants explained, and there is no reason why the choices should be restricted to two mutually exclusive accounts.

These disputes raise a deep question about just how significantly the means by which objectivity is to be secured can vary. But they do not raise a question about the nature of objectivity as the dispute is over how objectivity in the human sciences is best achieved, not over whether objectivity consists of something different in the natural and human sciences. What it consists of can be spelled out in operational terms: whether one is seeking to discover the causes of behavior or to interpret it, what we seek is an impartial account, one which could ideally be accepted by any subject on the basis of evidence and/or arguments.

The Limits of Objectivity

It is a hallmark of objectivity that one compares one's theory with the evidence, but sometimes it is difficult to distinguish

between the evidence for one's theory and one's expectations about what a plausible theory should or will reveal. One always judges a theory against what one already knows or believes to be the case, and while in some cases the theory may change one's beliefs and expectations, in others it may lead one to challenge the theory by trying to develop a viable alternative, for example. There may simply be no objective matter of fact, in particular cases, about which direction to go in: one direction may be no more objective than another. In other words, there is nothing objective about accepting evidence at face value: sometimes it is the right thing to do, sometimes not. In the face of potentially falsifying evidence, for example, it is often better to revise one's theory, to accommodate the theory to the evidence, than to abandon it. Some philosophers have tried to capture the conditions under which it is no longer productive to continue to revise a theory (e.g., Lakatos, 1972), while others have denied that this is possible (e.g., Feyerabend, 1974).

What these disputes suggest is that guidelines marking out how we are to secure objectivity are much more difficult to formulate than in the heyday of theories of scientific method, when it was assumed that comparison of theories with the evidence was all there was to the matter. But this is, of course, quite different from the claim that the securing of scientific results is not a matter of objectivity.

Abstract

This article elucidates the generally accepted idea that scientists should strive to be objective. It provides a definition of objective research, describes the evolving debate concerning objectivity, examines the foundations of objectivity in science, and discusses some of the principles of conduct relating to objectivity, such as honesty and openness. In exploring this subject, this article addresses several topics related to objectivity, such as error and bias, peer review, cooperation and trust in science, conflicts of interest, social responsibility, and the moral limits of objectivity.

Introduction

This article elucidates the generally accepted idea that scientists should strive to be objective. It provides a definition of 'objective research,' describes the evolving debate concerning objectivity, examines the foundations of objectivity in science, and discusses some of the principles of conduct relating to objectivity, such as honesty and openness. In exploring this subject, this article addresses several topics related to objectivity, such as error and bias, peer review, cooperation and trust in science, conflicts of interest, social responsibility, and the moral limits of objectivity.

What Is Objective Research?

The phrase 'objective research' has several different meanings in the social sciences and humanities. We often think of objective research as research that is *unbiased or impartial*. Thus, an objective researcher (or project, report, or study) is like a judge who attempts to give a fair hearing to both sides of a legal dispute. The objective judge listens to both sides of a dispute without giving undue consideration to either. We also think of objective research as *value-free*, i.e., as research that is unaffected by moral, economic, social, political, or religious values. Thus, an objective researcher is like a judge who attempts to make decisions based on legal and empirical evidence without allowing his values to affect his judgment and reasoning. We also think of objective research as *reliable or trustworthy*. Thus, an objective researcher is like a thermometer that reliably reports the temperature. We can trust the thermometer's report. Finally, we also think of objective research as research that is *factual or real*. Objective theories (hypotheses or concepts) are theories that correctly depict facts or real phenomena, and they can be contrasted with fiction, propaganda, speculation, and fraud. All of these conceptions of objective research capture some important aspects of our use of this phrase; there are a variety of ways of understanding objectivity (Harre and Krausz, 1996). For the purposes of this article, objective research can be defined as research that is: (1) unbiased or impartial, (2) value-free, (3) reliable or trustworthy, or (4) factual or real (Resnik, 2007).

The Evolving Debate about Objectivity

The notion that scientists have ethical duties to be objective is hardly a modern invention. Scientists and philosophers, who laid the foundations for the modern scientific method, such as Francis Bacon, Rene Descartes, Galileo Galilei, and William Harvey, all viewed science as objective inquiry. Editors of the first scientific journals instituted peer review in order to publish articles based on objective evidence and reliable methods (LaFollette, 1992). Charles Babbage (1970) was perhaps the first scientist to emphasize the ethical component of scientific objectivity in print. He coined the terms 'fudging,' 'cooking,' and 'trimming' to describe some of the unscrupulous research practices he observed in England in the 1800s. In the last half of the 1900s, powerful discoveries and inventions, such as atomic power, the computer, and genetic engineering, have compelled researchers to recognize the social impacts of science and technology and the relationship between objective inquiry and moral responsibility (Shrader-Frechette, 1994).

In the last two decades, politicians, the press, and the public have raised questions about scientific integrity and ethics as a result of highly publicized cases of misconduct in science and questionable research practices (Broad and Wade, 1993; Shamoo and Resnik, 2009). Some of these episodes include, allegations of fraud, plagiarism, misappropriation of funds, and exploitation of subordinates, as well as controversies concerning secrecy, conflicts of interest, patents, and the funding of science. In response to these concerns, funding agencies, professional associations, and research institutions have adopted codes of ethical conduct in science that address issues relating to objectivity and other aspects of scientific integrity and ethics (Sigma, 1986; American Association for the Advancement of Science, 1980; Panel on Scientific Responsibility and the Conduct of Research, 1992; Committee on the Conduct of Science, 2009; Shamoo and Resnik, 2009).

While this debate about ethical duties concerning objectivity was taking place, many scholars and scientists were questioning the idea that science is or can be objective. This controversy about the objectivity of science is also not new – the ancient Greek philosophers developed accounts of objective knowledge in response to sophistry and relativism – but its twentieth-century incarnation has spurred an extensive inquiry

into the nature of scientific method and practice. Inspired by Thomas Kuhn's monumental work on the history of science, *The Structure of Scientific Revolutions* (1962), scholars from the social sciences and humanities have challenged the traditional view of science as objective knowledge. According to these scholars, otherwise known as 'constructivists,' scientific research is strongly influenced by moral, economic, historical, social, political, or religious interests or values (Shapin and Shaffer, 1985; Latour and Woolgar, 1986). Defenders of the traditional view have responded to these critiques with their own arguments (Kitcher, 1993; Gross and Levitt, 1994; Haack, 2003; Resnik, 2007, 2009). These debates about the objectivity of science – the so-called 'science wars' – have migrated from the halls of academia to the outside world, and they have received considerable attention from the press.

For the purposes of this article, this debate is relevant insofar as it has some bearing on the ethical aspects of objectivity in research. With this in mind, it is important to realize that strong versions of constructivism may be incompatible with the idea that researchers have ethical obligations to be objective, since it makes little sense to claim that a person has an ethical obligation that he cannot fulfill. If it is impossible to at least strive to be objective, then the claim that researchers have ethical duties to be objective is moot (Resnik, 1998). While it is important to acknowledge and understand factors that can undermine or compromise objectivity in research, this article will assume that it is at least possible for researchers to strive to be objective, even if they often fall short of this ideal (Resnik, 2007).

Foundations of Research Ethics

Ethical duties in science stem from two main sources: (1) the scientific profession itself, and (2) society at large (Resnik, 1998). Ethical standards (or norms) promote the aims and goals of science in several ways. Many standards promote the advancement of human knowledge. For example, honesty in science is important in obtaining truth and avoiding error and deception. Other ethical standards play a key role in promoting collaboration and trust among scientists by creating institutional structures that direct individual interests toward common goals (Merton, 1973). For example, authorship practices reward researchers for their efforts and ingenuity, insure that publications meet standards of quality and originality, and hold researchers accountable for their contributions (Shamoo and Resnik, 2009).

Scientists also should adhere to ethical standards in order to promote social values, uphold the public's trust in science, and secure the public's support for research. For example, data fabrication can lead to harmful social consequences, especially if the fabricated results pertain to applied sciences like medicine or engineering. Data fabrication can also be construed as a form of lying, which is widely regarded as immoral. Data fabrication violates the public's trust in science because the public trusts that scientists will not fake data. Finally, fabrication can undermine the public's support for science if people become concerned about unethical conduct among researchers and decide to shift government funds to other programs, such as education or health care.

Ethical Principles and Objectivity

There are a variety of ethical principles (or standards) that promote objectivity in research. The principles discussed below should be viewed as general guidelines instead of absolute rules. They must be elaborated, assessed, and interpreted before they can be applied to particular situations or cases.

Honesty

The principle of honesty implies a general prohibition against falsifying, fabricating, or misrepresenting data, results, or other types of information pertaining to scientific publication. Honesty applies to a variety of other aspects of research, such as grant proposals, peer review, personnel actions, accounting and finance, expert testimony, informed consent, media relations, and public education. As mentioned previously, honesty plays a key role in the search for knowledge and in promoting cooperation and trust among researchers. Few scientists or scholars dispute the importance of honesty and most people understand what it means to fabricate or falsify information pertaining to research. However, a few points of clarification will be helpful.

Error, Bias, and Disagreement

First, it is important to distinguish between dishonest research and error. Dishonesty implies the intent to deceive; error does not. Making an honest mistake in recording or analyzing data should not be equated to faking data. Although errors and dishonesty often have similar results; i.e., the deception of an audience, they arise from different motives. However, scientists also have an obligation to avoid making errors, since errors can also damage the quest for knowledge and undermine cooperation and trust among researchers. Although mistakes are, and always will be, a part of science – scientists are human beings, after all – excessive or egregious errors should be denounced as a form of negligence, since these errors have detrimental effects on research or its practical applications (Shamoo and Resnik, 2009).

Scientists have an obligation to prevent errors by carefully scrutinizing and reviewing their own work and the work of others. Although some errors result from haste or sloppiness, more subtle follies are due to systematic errors (or biases) and self-deception. For example, since the 1800s, racial and ethnic biases have plagued research on human intelligence. More recently, self-deception (or simple carelessness) was probably at work in the cold fusion research conducted by Stanley Pons and Martin Fleischmann, because they did not describe their methods in sufficient details for others to replicate their experiments (Shamoo and Resnik, 2009). Scientists also have a responsibility for reducing the effects of error by publishing errata, corrections, retractions, or apologies. Although the peer review system is not perfect, it can play an important role in reducing errors. Hence, reviewers and editors have ethical responsibilities pertaining to objectivity (LaFollette, 1992).

It is also important to distinguish between dishonesty and disagreement. Researchers often have fundamental disagreements about methods, concepts, and theories. Scientists may

disagree about research results (or their significance) without viewing their opponents as dishonest. Before an act can be judged to be dishonest, researchers must have some agreement on what constitutes the honest application of methods and concepts.

Misrepresentation of Data

The concept of 'misrepresentation,' unlike 'fabrication' and 'falsification,' is neither clear nor uncontroversial. Most scientists will agree that fabrication is making up data and falsification is changing data. But what does it mean to misrepresent data? As a minimal answer to this question, one can define 'misrepresentation of data' as 'communicating honestly reported data in a deceptive manner.' But what is deceptive communication? The use of statistics presents researchers with numerous opportunities to misrepresent data. For example, one might use a statistical technique, such as multiple regression or the analysis of variance, to make one's results appear more significant or convincing than they really are. Or one might eliminate (or trim) outliers when 'cleaning up' raw data. Other ways of misrepresenting data include: drawing unwarranted inference from data; creating deceptive graphs, figures, or images; not publishing all of the data; and using overly suggestive language for rhetorical effect.

However, since researchers often disagree about the proper use of statistical techniques and other means of representing data, the line between misrepresentation of data and 'disagreement about research methods' is often blurry. Since 'misrepresentation' is difficult to define, many organizations have refused to characterize misrepresenting data as a form of scientific misconduct. On the other hand, it is important to call attention to the problem of misrepresenting data, if one is concerned about promoting objectivity in research, since many of science's errors and biases result from the misrepresentation of data (Shamoo and Resnik, 2009).

Conflicts of Interest

In order to promote objectivity in research, it is important for scientists to minimize the effects of financial, personal, professional, and political interests that may potentially undermine their ability to conduct and evaluate research. Conflict of interest has emerged as an important ethical concern in science in this century as many researchers now have significant financial interests in their work (Macrina, 1995; Resnik, 2007). Private support for research and development (R&D) has risen steadily since 1970. Today, industry provides more than 60% of R&D funding in the United States alone, and it is expected that the trend toward the privatization of research will continue. Scientists working in the private sector receive remuneration in the form of salary, stock options, or royalties. Even researchers funded by governments or universities can have significant financial interests in the form of patents or copyrights. Although financial, and other, interests do not invalidate research – good research can still occur in troublesome circumstances – research that is conducted when conflicts exist is more likely to be biased or unreliable. For example, a scientist whose research is sponsored by a pharmaceutical company is more likely to distort results so that they favor the company than a scientist who is not working for the company. Even when research is not biased, the presence of a significant conflict can create the perception of a bias and distrust. For example, if people learn that a food company has sponsored research demonstrating the health benefits of its fat-free potato chip, they may believe that the research is biased, even if it is not. Conflicts of interest can arise in experimental design, publication, peer review, personnel decisions, expert testimony, media interviews, and other aspects of science (Resnik, 1998, 2007).

How should scientists deal with conflicts of interest? First, scientists should disclose conflicts of interest to those parties who may be affected by these conflicts. Most journals and funding organizations now require researchers to disclose sources of funding and conflicts of interest. Sometimes these disclosures are made available to the public when articles are published. Disclosure can help buffer the impact of bias by allowing reviewers, scientists, and the lay public to scrutinize and question research that may be affected by economic, social, or political interests. Second, although it is not possible to avoid all conflicts of interest, researchers have a duty to avoid those conflicts that cannot be corrected by peer review or may have a dramatic impact on science or society. For example, researchers should not review a grant application if the applicant is a close friend or bitter enemy. The decision to avoid a conflict of interest, also known as 'recusal,' can promote objectivity by removing a researcher from a situation that could create a bias or the perception of bias.

Openness

Since openness provides scientists with a reliable defense against error, bias, self-deception, dishonesty, and other phenomena that can threaten objectivity, it is an important ethical principle in research. Openness promotes objectivity in several ways. First, it enables researchers to criticize each other's work. Criticism can occur before, during, or after peer review. Frequently, the most important criticism takes place before an idea appears in print. Second, openness helps researchers to make effective use of human and technological resources. Problems can be solved more effectively when researchers work together than when they work in isolation (Merton, 1973). Third, openness allows the public to learn about research and take effective measures to protect public health and safety, society, and the environment.

Although openness is an important ethical principle in research, it often conflicts with personal or institutional interests. Sometimes researchers refuse to share data in order to protect scientific priority or intellectual property rights. For example, a researcher who is developing a new product may decide not to share preliminary data until he or she has applied for a patent. A researcher who discovers a new phenomenon may not disclose the discovery until the paper has been accepted for publication. Sometimes researchers refuse to share data in order to protect their reputations. For example, a scientist may decide not to share preliminary results from a study until they have had enough time to verify

and analyze those results. Researchers may refuse to share data because they have signed a contract with a corporate sponsor not to disclose data without prior authorization. Also, need to be taken to protect the privacy and confidentiality of human research participants. Since many different parties – government, industry, colleagues, the media – may seek to obtain scientific information, it is likely that researchers will often face difficult choices when deciding how and when to share information.

The Moral Limits of Objectivity

While objectivity is one of science's most important principles, it should be acknowledged that this norm sometimes conflicts with other ethical duties, such as the obligation to protect human subjects and social responsibility (Shrader-Frechette, 1994). For example, anthropologists may refuse to publish or disclose information in order to protect and promote the welfare of the human populations they are studying. In psychology, researchers have a duty to keep information about human subjects confidential in order to protect their privacy, dignity, and autonomy. An ecologist who is interviewed by the media must choose between their desire to advocate for the environment and their scientific duties to remain objective. Although scientists should strive to be objective, there are some situations where scientists should relax their commitment to objectivity in order to promote other moral and social values.

Abstract

This article is an overview of philosophical conceptions of objectivity, and it is divided into three parts. First, it describes metaphysical objectivity, which concerns the extent to which the existence and character of some class of entities depends on the states of mind of persons. Second, it describes epistemological objectivity, which concerns the extent to which we are capable of achieving knowledge about those things that are objective. Finally, it shows that metaphysical and epistemological considerations of objectivity are also the focus of sharp critiques by post-positivist and feminist philosophers, who focus on the procedural nature of objectivity, and of an emergent historical–epistemological way of analyzing objectivity that claims to be of primary philosophical relevance.

Traditionally, there are two main kinds of philosophical questions about objectivity, mostly debated in Anglo-American philosophy, which in turn takes up some of the classical features of that notion: metaphysical and epistemological.

Metaphysical objectivity concerns the extent to which the existence and character of some class of entities depends on the states of mind of persons (i.e., their knowledge, judgment, belief, perception, or response). Epistemological objectivity concerns the extent to which we are capable of achieving knowledge about those things that are metaphysically objective. But metaphysical and epistemological considerations of objectivity are also the focus of sharp critiques by post-positivist and feminist philosophers, who focused on the procedural nature of objectivity; more recently, a historical–epistemological way of analyzing objectivity also emerged that claims to be of primary philosophical relevance. Various streams of contemporary thought thus put into question the metaphysical and traditional notion of objectivity following a variety of purposes: some of them want to substitute it with a more humble and 'communitarian' concept of objectivity; some want to destroy it; some want to understand how it historically came into being.

Metaphysical Objectivity

An entity (or a class of entities) is metaphysically objective if its existence and character are independent of the human mind. This 'independence requirement' is central to metaphysical objectivity (Brower, 1993; Sober, 1982), though its proper interpretation raises two important questions: first, in what way must a metaphysically objective thing be 'independent' of the human mind; and second, how much independence of the relevant kind is required?

What Kind of Independence?

The existence and character of some entity might be independent of the human mind in three senses: causally, constitutionally, and cognitively. Only the last two will matter for metaphysical objectivity. An entity is causally independent of the human mind as long as the causal trajectory producing it did not involve the human mind. Shoes, for example, are causally dependent on the human mind because the existence and character of any particular pair of shoes depends causally on a cobbler having had certain beliefs and desires (e.g., a desire to make a particular kind of shoe, and true beliefs about what needed to be done to produce such shoes). By contrast, the existence and character of the earth is causally independent of the human mind: no human intentions played a causal role in bringing about the existence of the earth or its specific character. Metaphysical objectivity, however, does not require causal independence. Even entities that are causally dependent on the human mind can be mind-independent in one of the other two senses (discussed later), and thus still be metaphysically objective. An entity is constitutionally independent of the human mind if its existence and character are not constituted by or identical with the mind. The claim that some entity is metaphysically objective almost always involves denying its constitutional dependence on the mind. The exception is for psychological entities (e.g., beliefs, desires, emotions): such things cannot be constitutionally independent of the mind because they just are facets of the mind. Yet surely psychological facts may also be metaphysically objective. If so, it must be in the final sense of 'independence' from the mind. An entity is cognitively independent of the human mind if its existence and character does not depend on any cognizing state of persons, for example, belief, sensory perception, judgment, response, and so forth. (A 'cognizing' state is one that is receptive to features of the world and thus is a potential source of knowledge of the world.) A metaphysically objective thing is, accordingly, what it is independent of what anyone believes or would be justified in believing about it (or what anyone perceives it to be or would perceive it to be under certain conditions, etc.). On this account, psychological facts about a person are metaphysically objective in virtue of not depending on what an observer of that person believes or would be justified in believing about that person's psychological state. Any kind of metaphysically objective fact (except for psychological facts) must necessarily be constitutionally independent of the mind. All metaphysically objective facts must also be cognitively independent. The common-sense picture of

the natural world presumes that its contents are metaphysically objective in this sense: ordinary people think that atoms and zebras and sulfur are not simply identical with the mind, and that they are what they are independent of what people may believe or be justified in believing about them. Science, then, aspires to epistemological objectivity by trying to accurately depict the way things (objectively) are.

How Much Independence?

There can be degrees of cognitive independence, and thus degrees of objectivity that may be distinguished; not everything that is objective may prove to be objective in the sense in which common sense understands the constituent elements of the natural world to be objective. The crucial notion for cognitive independence is independence from the cognizing states of persons: beliefs, sensory perceptions, judgments, responses, and the like. It is possible, then, to distinguish four kinds of claims about objectivity. According to *subjectivism*, what seems right to the cognizer determines what is right. According to *minimal objectivism*, what seems right to the community of cognizers determines what is right. According to *modest objectivism*, what seems right to cognizers under appropriate or ideal conditions determines what is right. According to *strong objectivism*, what seems right to cognizers never determines what is right. Subjectivism and strong objectivism represent the two classical and opposed philosophical positions of antiquity: Protagoras held that "man is the measure of all things" (subjectivism) (Plato, *Theaetetus* *152a, *166a–*8b), while Plato embraced a kind of strong objectivism (Plato, *Phaedo* *741–*75b, *Republic* *475–*80, *508d-e). The Protagorean position denies the objectivity of the world and everything in it: whatever each individual takes to be the case is the case (for that individual), and thus the existence and character of any particular thing depends (epistemically) on the (individual) human mind. By contrast, the Platonist affirms the complete and absolute objectivity of the world: what really is the case about the world is never fixed by what any person or all persons believe, has (or have) reasons to believe, or could have reasons to believe. Mistake, on a global scale, even under ideal epistemic conditions, is a possibility for the Platonist. Platonists are often called 'idealists,' but they believe in the absolute reality of Ideas, so this latter position can be described as 'realism,' or better, 'metaphysical realism.' Minimal objectivism and modest objectivism occupy conceptual space between these two familiar, historical positions. Minimal objectivism holds that whatever the community of cognizers takes to be the case is the case. This view, like its pure Protagorean cousin, issues in a kind of relativism (what is the case is relative to a particular community of cognizers), but by abstracting away from the subjectivity of the individual cognizer, it introduces a minimum amount of objectivity. It is also a kind of objectivity with some useful domains of application. What is and is not fashionable, for example, is probably minimally objective. What seems right to John about what is fashionable can be objectively wrong: John may be out of sync with the styles of his community, and thus it would be correct to say, "John is mistaken in thinking that a plaid shirt and striped pants go well together." But it does not seem that the entire community can be wrong about what is fashionable: in that sense, what seems right to the community determines what really is fashionable.

In most domains, however, minimal objectivity would be viewed as too close to subjectivism for comfort. Modest objectivity thus abstracts even further away from dependence on actual cognizers, individual or communal. Something is modestly objective if its existence and character depends only on what cognizers would believe under certain idealized conditions for cognition, conditions like full information and evidence, perfect rationality, and the like. (By hypothesis, under ideal conditions, all cognizers would come to the same belief about things.) Everyone on the planet can be wrong in his or her beliefs about a modestly objective entity; beliefs formed under ideal epistemic conditions, however, can never be wrong. This latter point is what differentiates modest from strong objectivity. Some philosophers have defended the idea that the truth about the world is at best modestly objective (e.g., the doctrine Putnam calls 'internal realism' in Putnam, 1981): what is true in any domain is simply whatever inquirers would agree upon under epistemically ideal conditions.

Alternative Metaphysical Conceptions

In the so-called continental tradition, the philosophical movement that had the greatest impact on the contemporary philosophy of objectivity, also by establishing a solid base for various forms of criticism of scientific objectivity, is phenomenology. Phenomenology gave birth to a variety of ways of thinking, but its founder is commonly recognized as Edmund Husserl.

The starting point of phenomenology was the debate on the status of the objects of thought and logic between those who thought them to be purely logic – objective – entities (Frege) and those who believed them to be psychological – subjective – entities (Brentano). Husserl criticized the psychology-oriented position, but maintained that concepts and objects have their origin in the 'intentional' activity of the mind: every object must correspond to the conscience of it. In other words, Husserl's problem was to conciliate the universal and objective nature of logical objects with the subjective experience of the cognizing mind. Husserl's phenomenology of the experience of the mind did not want to reduce objects to psychological states, nor to separate objective contents from the concrete activity of the mind, and he claimed that what had to be investigated was the 'phenomenon' itself, not conceived as opposed to a thing in itself (Kant), but as the way in which reality manifests itself in the mind. In order to do so, Husserl proposed a method he called *epoché*, consisting in freeing oneself from all the psychological and logical assumptions and describing the pure experience of objective reality as it appeared in the mind, thus embracing a strong idea of objectivity as a description of the original and essential correlation between the mind and the external world. In the view of its founder, phenomenology had to provide the foundation of all scientific thought (Husserl, 1970).

Husserl's philosophy later took the path of an extreme transcendentalism, embracing the absolute reality of the mind as a sort of renewed Cartesian *cogito*, while his early works

became the basis for the development of Heidegger's ontology. But by the 1930s almost all the members of the phenomenological school shared the view that objective knowledge, in the form of 'science' – often called 'objectivism' – became a mere technical activity more and more separated from the essence of philosophy and of authentic knowledge. Influenced by historicist thinkers such as Willhelm Dilthey, and by Heidegger's early existential analysis, Husserl and the phenomenologists elaborated the concept of the 'lifeworld,' a world of intersubjective concrete experience of reality that is the background, and the source, of all human activity (science and objective knowledge included). This preconceptual historical and social world of original and shared intersubjective experiences and activities is the basis of scientific objectivity, and as such it allowed phenomenologists to criticize science for detaching itself from the lifeworld and becoming a hollow and dangerous technological dominion over the natural and human world. Before becoming the explicit focus of natural science, the world is this set of shared horizons of meanings and experiences; objectivity was possible only insofar it remained connected to the intersubjective exchanges it came from (Husserl, 1970a). This does not mean that phenomenological thought has been antiscientific, but rather that it opened the way to procedural conceptions of scientific knowledge and objectivity, which could also be thought of in social, historical, and political terms.

Epistemological Objectivity

The demand for epistemological objectivity is the demand to be free of bias and other subjective factors that distort cognition, that prevent the things being cognized from presenting themselves as they really (metaphysically) are. More precisely, epistemological objectivity requires that the cognitive processes and mechanisms by which beliefs about the world are formed be constituted in such a way that they at least tend toward the production of accurate representations of how things are. Notice that epistemological objectivity does not require that cognitive processes always yield true representations: that would demand more than is attainable and more than is even expected. Epistemological objectivity obtains when either of the following is true: (1) the cognitive processes at issue reliably arrive at accurate representations, or (2) the cognitive processes are free of factors that are known to produce inaccurate representations. The obstacles to epistemological objectivity will vary with the domain under consideration. In the sciences generally, and the social sciences in particular, 'values' are often thought to present a special obstacle to epistemological objectivity insofar as they influence the choice of research topics and, most seriously, the selection and evaluation of evidence (Weber, 1949). As one author explains: "Values are thought to damage inquiry epistemically because they are held to be subjective – they come from us, not the world. Therefore, to allow values to influence inquiry into the nature of the world is to allow such inquiry to be subject to a control other than the world itself" (Railton, 1985: p. 818).

Epistemic values or norms – for example, norms about when evidence warrants belief – must of course play a role in all scientific inquiry; the worry is about nonepistemic values or norms, like the political ideology of the inquirer or the political climate in which inquiry takes place. Yet even here the effect on objectivity depends on the context and the precise role values play in inquiry. For example, where the political climate is hostile to the discovery of certain kinds of objective truths, only those inquirers motivated by a contrarian political ideology themselves are likely to pursue those objective truths (Miller, 1991). Here, of course, values supply a motive for allowing 'the nature of the world' to control the course of inquiry, rather than interceding and distorting cognition.

More generally, one "need not require freedom from all value and bias in order to have objective inquiry" since "there may yet exist mechanisms of belief formation that incorporate feedback from the object to the inquiring subject" (Railton, 1985: p. 818). The mechanism at issue is causal: metaphysically objective things make themselves felt causally, whatever our theoretical preconceptions and values. This, however, is merely an external criterion for objectivity, and does not yet show how inquirers could determine whether or not their inquiry is epistemologically objective.

Here, however, inquirers might look for certain familiar markers of epistemological objectivity, like the existence of intersubjective agreement in judgment, the publicity of evidence and standards of proof, and the reproducibility of the evidence for a judgment by different inquirers: "when these conditions are met, subjective contributions and biases will be excluded as far as possible" (Railton, 1985: p. 818). That physics constitutes a cross-cultural, global community of inquirers strongly suggests that it is epistemologically objective: if it were not, then one would expect local differences (in interests, ideology, and the like) to lead to markedly different discourses of physics.

Epistemological Critiques

The epistemology of objectivity has proved to be a fruitful field for critiques and different approaches aiming at reforming, correcting, or destroying the metaphysical notion of objectivity. In the first place, metaphysical thinking seems to imply as its epistemological correlative, a 'view from nowhere' (Nagel, 1997). Secondly, objectivity has been conceived as a point of attraction of a series of values and attitudes like detachment, impartiality, neutrality, lack of biases, and so forth, which should guide science toward truth via objectivity. Third, objectivity has been conceived in this way as coinciding with an ahistorical core of truth, rationality, and reality. Post-positivistic philosophy put into question all these assumptions: the idea of the dual structure of knowledge (scheme and reality, or language and empirical observation); the ahistorical nature of objective knowledge (knowledge is a historical process and as such it does not follow a linear line of progress); and the supposed moral neutrality of objective knowledge (objective knowledge is an intersubjective process, constitutively biased, dependent upon social and cultural assumptions).

Already in the 1930s the French philosopher and historian of science Gaston Bachelard put into question these three assumptions. In a series of very influential texts, he wrote a 'psychoanalysis of objective knowledge' that conceived objectivity in historical, dynamic, and procedural terms. The
